```

Method: TradovateAccount.__init__

```
def __init__(self, username, password, pair_id=None, trading_mode='Simulation')
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **raise** — Raises an exception explicitly. Either signals an invalid argument the caller should fix, or re-raises after logging.
- **__init__** — The constructor. Runs after Python has allocated the instance; assigns starting attribute values to self.

Step by step (top-level body)

1. Assigns `self.username = username`.
2. Assigns `self.password = password`.
3. Assigns `self.pair_id = pair_id` or 'default'.
4. Assigns `self.trading_mode = trading_mode`.
5. Assigns `self.logged_in = False`.
6. Assigns `self.driver = None`.
7. Assigns `self.first_trade_attempted = False`.
8. Assigns `self._first_stats_fetch = True`.
9. Assigns `self._placing_order = False`.
10. Assigns `self._login_timestamp = None`.
11. Assigns `self.lock = threading.RLock()`.
12. Assigns `instance_key = f'{username}_{self.pair_id}'`.
13. **if** `instance_key` in `self._chrome_instances`: branches conditionally.
14. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def __init__(self, username, password, pair_id=None, trading_mode="Simulation"):
    self.username = username
    self.password = password
    self.pair_id = pair_id or "default"
    self.trading_mode = trading_mode # "Simulation" or "Live Trading"
    self.logged_in = False
    self.driver = None
    self.first_trade_attempted = False
    self._first_stats_fetch = True
    self._placing_order = False # Flag to block stats fetching during order placement
    self._login_timestamp = None # Track when we logged in for debugging
    self.lock = threading.RLock() # Thread safety for Selenium operations

    # Create unique instance key using both username and pair_id

```

Method: TradovateAccount._force_trade_override

```
def _force_trade_override(self, symbol, qty, side, tp=None, sl=None, override_reason='Emergency override')
```

Emergency method to force a trade execution bypassing blueprint validation. Use only in critical situations where manual override is absolutely necessary. Args: symbol (str): Trading symbol qty (int): Quantity side (str): "buy" or "sell" tp (int, optional): Take profit ticks sl (int, optional): Stop loss ticks override_reason (str): Reason for override (logged for audit) Returns: bool: Success status

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Calls `logging.warning(...)` for its side effect.
2. Calls `logging.warning(...)` for its side effect.
3. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

def _force_trade_override(self, symbol, qty, side, tp=None, sl=None, override_reason="Emergency override"):
    """

```
return False
```

Method: TradovateAccount._place_order_side_unvalidated

```
def _place_order_side_unvalidated(self, symbol, qty, side, tp=None, sl=None, on_click=None,
    skip_positions_refresh=False)
```

Original order placement method without blueprint validation. Used internally for emergency overrides.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `original_strict_mode = os.getenv('BLUEPRINT_STRICT_MODE')`.
2. Assigns `os.environ['BLUEPRINT_STRICT_MODE'] = 'false'`.
3. **try** block with 1 **except** clause, plus a **finally**.

Code (copy-paste safe)

```
def _place_order_side_unvalidated(self, symbol, qty, side, tp=None, sl=None, on_click=None,
    skip_positions_refresh=False):
    """
    Original order placement method without blueprint validation.
    Used internally for emergency overrides.
    """
    # This would be the original _place_order_side logic without validation
    # For now, we'll just call the existing method but skip the validation part
    # In a full implementation, this would duplicate the order placement logic

    # Temporarily disable validation by setting environment variable
    original_strict_mode = os.getenv("BLUEPRINT_STRICT_MODE")
    os.environ["BLUEPRINT_STRICT_MODE"] = "false"

    try:
        result = self._place_order_side(symbol, qty, side, tp, sl, on_click, skip_positions_refresh)
        return True
    except Exception as e:
        logging.error(f"[ALARM] UNVALIDATED TRADE FAILED: {e}")
        return False
    finally:
        # Restore original setting
        if original_strict_mode is not None:
            os.environ["BLUEPRINT_STRICT_MODE"] = original_strict_mode
        else:
            os.environ.pop("BLUEPRINT_STRICT_MODE", None)
```

Method: TradovateAccount.get_validation_status

```
def get_validation_status(self)
```

Get current blueprint validation configuration status. Returns: dict: Validation configuration and status

Step by step (top-level body)

1. **return** {'strict_mode': os.getenv('BLUEPRINT_STRICT_MODE', 'true').lower()

Code (copy-paste safe)

```
def get_validation_status(self):
    """
    Get current blueprint validation configuration status.

    Returns:
        dict: Validation configuration and status
    """
    return {
        "strict_mode": os.getenv("BLUEPRINT_STRICT_MODE", "true").lower() == "true",
        "selected_prop_firm": os.getenv("SELECTED_PROP_FIRM", "MFFU"),
        "trading_phase": os.getenv("TRADING_PHASE", "challenge_trade1"),
        "account_size": os.getenv("ACCOUNT_SIZE", "50k"),
        "validation_enabled": True
    }
```

Method: TradovateAccount.login

```
def login(self)
    Perform full login sequence with robust error handling and retries.
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **raise** — Raises an exception explicitly. Either signals an invalid argument the caller should fix, or re-raises after logging.

Step by step (top-level body)

1. **with self.lock**: enters a context manager.

Code (copy-paste safe)

```
def login(self):
    """
    Perform full login sequence with robust error handling and retries.
    """
    # Acquire lock to prevent stats fetching during login
    with self.lock:
        if self.logged_in:

```

Method: TradovateAccount._fast_input_with_validation

```
def _fast_input_with_validation(self, element, value, field_name='field')
```

Enhanced input method using proven Selenium approach that preserves text after typing

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

    raise Exception(f"Different broker simulation access failed: {e}")

```

Method: TradovateAccount._launch_simulation_tab_fallback_new

```
def _launch_simulation_tab_fallback_new(self)
```

New fallback: Try tabbing to the button and using Enter key.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

- **raise** — Raises an exception explicitly. Either signals an invalid argument the caller should fix, or re-raises after logging.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def _launch_simulation_tab_fallback_new(self):
    """New fallback: Try tabbing to the button and using Enter key."""
    try:
        # First try to find any button that might be the simulation button

        try:
            print(f"■ THREAD-EXEC] Clicking BUY button...")
            self._do_place_order("buy", on_click=None, skip_positions_refresh=skip_positions_refresh)

```

```

        print(f"■ [■ THREAD-EXEC] BUY button clicked")
    except Exception as e:
        print(f"■ [■ THREAD-EXEC] Execution failed: {e}")
        raise

```

Method: TradovateAccount.prepare_sell_order

```
def prepare_sell_order(self, symbol, qty, tp=None, sl=None)
```

THREADING OPTIMIZATION: Prepare SELL order (symbol search, quantity, ATM) WITHOUT clicking button. Use this before threading to minimize time inside parallel execution. Returns: True if preparation successful, False otherwise

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **with self.lock:** enters a context manager.

Code (copy-paste safe)

```

def prepare_sell_order(self, symbol, qty, tp=None, sl=None):
    """
    THREADING OPTIMIZATION: Prepare SELL order (symbol search, quantity, ATM) WITHOUT clicking button
    Use this before threading to minimize time inside parallel execution.

    Returns: True if preparation successful, False otherwise
    """
    with self.lock:
        try:
            print(f"■ [■ PRE-THREAD] Preparing Tradovate SELL order: {symbol} x{qty}")

            # Quick interface check
            current_url = self.driver.current_url
            if not current_url or "tradovate" not in current_url:
                print(f"■ [■ PRE-THREAD] Not on Tradovate page, logging in...")
                self.login()

            # Prepare order (slow operations done before threading)
            self._wait_for_no_overlay(timeout=0.2)
            self._select_symbol(symbol)
            self._set_quantity(qty)
            self._setup_atm(tp, sl)

            print(f"■ [■ PRE-THREAD] Order prepared - ready for button click")
            return True

        except Exception as e:
            print(f"■ [■ PRE-THREAD] Preparation failed: {e}")

```

```
return False
```

Method: TradovateAccount.execute_prepared_sell_order

```
def execute_prepared_sell_order(self, skip_positions_refresh=False)
```

THREADING OPTIMIZATION: Execute already-prepared SELL order (just click button). Call prepare_sell_order() first, then use this inside threading for instant execution. Returns: None (raises exception on failure)

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **raise** — Raises an exception explicitly. Either signals an invalid argument the caller should fix, or re-raises after logging.

Step by step (top-level body)

1. **with self.lock:** enters a context manager.

Code (copy-paste safe)

```
def execute_prepared_sell_order(self, skip_positions_refresh=False):
    """
    THREADING OPTIMIZATION: Execute already-prepared SELL order (just click button).
    Call prepare_sell_order() first, then use this inside threading for instant execution.

    Returns: None (raises exception on failure)
    """
    with self.lock:
        try:
            print(f"■ THREAD-EXEC Clicking SELL button...")
            self._do_place_order("sell", on_click=None, skip_positions_refresh=skip_positions_refresh)
            print(f"■ [■ THREAD-EXEC] SELL button clicked")
        except Exception as e:
            print(f"■ THREAD-EXEC Execution failed: {e}")
            raise
```

Method: TradovateAccount.get_active_account

```
def get_active_account(self)
```

Get the full (unmasked) account number currently active in the Tradovate UI. DOM structure: div.account-selector-wrapper div.account-selector.dropdown div[data-toggle="dropdown"] div.account > div.name > div ← contains account number ul.dropdown-menu li.selected > a.account > div.name > div.main ← selected account Returns: str: The account number string (e.g. "FTDFYSLX50349776193"), or None.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **if not self.driver:** branches conditionally.
2. **try** block with 1 **except** clause.
3. **return None**.

Code (copy-paste safe)

```
def get_active_account(self):

```

Method: TradovateAccount.switch_account

```
def switch_account(self, target_account)
```

Switch to a specific sub-account via Tradovate's account dropdown. DOM structure (from live Tradovate page): `div.account-selector-wrapper` `div.account-selector.dropdown` `div[data-toggle="dropdown"]` ← *CLICK to open dropdown* `ul.dropdown-menu` ← *dropdown list* `li > a.account` ← *each account entry (skip a.logout)* `div.name > div.main` ← *account number text* Args: `target_account`: Account number string (or unique substring) to select. Returns: `bool`: True if account was switched (or already active), False on failure.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. `if not self.driver or not target_account`: branches conditionally.
2. Imports `re` (lazy import inside the function).
3. Assigns `target_account = str(target_account).strip()`.
4. Assigns `target_lower = target_account.lower()`.
5. Assigns `digit_match = _re.search('(\d{5,})$', target_account)`.
6. Assigns `digit_suffix = digit_match.group(1)` if `digit_match` else `None`.
7. Calls `print(...)` for its side effect.
8. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def switch_account(self, target_account):
    """Switch to a specific sub-account via Tradovate's account dropdown.

```

Method: TradovateAccount.verify_active_account

```
def verify_active_account(self, expected_account)
```

Verify that the currently active account matches the expected one. Args: expected_account: Expected account number (or substring). Returns: bool: True if the active account matches, False otherwise.

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **if** not expected_account: branches conditionally.
2. Assigns current = self.get_active_account().
3. **if** not current: branches conditionally.
4. Assigns expected_lower = str(expected_account).strip().lower().
5. **if** expected_lower in current.lower(): branches conditionally.
6. Calls logging.warning(...) for its side effect.
7. **return** False.

Code (copy-paste safe)

```

def verify_active_account(self, expected_account):
    """Verify that the currently active account matches the expected one.

    Args:
        expected_account: Expected account number (or substring).

    Returns:
        bool: True if the active account matches, False otherwise.
    """
    if not expected_account:
        return True # No expectation set, skip check

    current = self.get_active_account()

```

```

if not current:
    logging.warning(f"[ACCOUNT] Cannot verify – unable to read active account")
    return False

expected_lower = str(expected_account).strip().lower()
if expected_lower in current.lower():
    logging.info(f"[ACCOUNT] Verified: active={current}, expected={expected_account}")
    return True

logging.warning(f"[ACCOUNT] MISMATCH: active={current}, expected={expected_account}")
return False

```

Method: TradovateAccount.buy_market

```

def buy_market(self, symbol=None, qty=1, tp=None, sl=None, on_click=None, skip_positions_refresh=False,
    prop_firm=None, phase=None, account_size=None, expected_account=None)

```

Step by step (top-level body)

1. Calls self._place_order_side(...) for its side effect.

Code (copy-paste safe)

```

def buy_market(self, symbol=None, qty=1, tp=None, sl=None, on_click=None, skip_positions_refresh=False,
    prop_firm=None, phase=None, account_size=None, expected_account=None):
    self._place_order_side(symbol, qty, "buy", tp, sl, on_click=on_click,
        skip_positions_refresh=skip_positions_refresh, prop_firm=prop_firm, phase=phase, account_size=account_size)

```

Method: TradovateAccount.sell_market

```

def sell_market(self, symbol=None, qty=1, tp=None, sl=None, on_click=None, skip_positions_refresh=False,
    prop_firm=None, phase=None, account_size=None, expected_account=None)

```

Step by step (top-level body)

1. Calls self._place_order_side(...) for its side effect.

Code (copy-paste safe)

```

def sell_market(self, symbol=None, qty=1, tp=None, sl=None, on_click=None, skip_positions_refresh=False,
    prop_firm=None, phase=None, account_size=None, expected_account=None):
    self._place_order_side(symbol, qty, "sell", tp, sl, on_click=on_click,
        skip_positions_refresh=skip_positions_refresh, prop_firm=prop_firm, phase=phase, account_size=account_size)

```

Method: TradovateAccount._set_quantity

```

def _set_quantity(self, qty)

```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **raise** — Raises an exception explicitly. Either signals an invalid argument the caller should fix, or re-raises after logging.

Step by step (top-level body)

1. Calls `print(...)` for its side effect.
2. `try` block with 1 `except` clause.

Code (copy-paste safe)

```
def _set_quantity(self, qty):
    print(f"[ZAP] Setting quantity: {qty}")
    try:
        qty_input = WebDriverWait(self.driver, 3).until(
            EC.element_to_be_clickable((By.XPATH,
                "//div[contains(@class, 'trading-ticket-main-entry')]/div[contains(@class, 'qty')]/"
            ))

        # SPEED OPTIMIZATION: Check if quantity is already correct first
        current_qty = qty_input.get_attribute("value") or ""
        if current_qty.strip() == str(qty).strip():
            print(f"[ZAP] Quantity {qty} already set - skipping update")
            return

        # Update quantity with proper input clearing delays
        qty_input.click()
        time.sleep(0.1) # Increased delay for reliable clearing
        qty_input.send_keys(Keys.CONTROL + "a")
        qty_input.send_keys(Keys.DELETE)
        time.sleep(0.1) # Increased delay before typing new value
        qty_input.send_keys(str(qty))

        print(f"[ZAP] Quantity updated to {qty}")

    except Exception as e:
        print(f"[WARNING] Quantity setting failed: {e}")
        raise
```

Method: TradovateAccount._setup_atm

```
def _setup_atm(self, tp=None, sl=None)
```

Optimized ATM setup with smart input checking

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns `tp = tp` if `tp` is not `None` else `os.getenv('TRADOVATE_TAKEPROFIT....')`
2. Assigns `sl = sl` if `sl` is not `None` else `os.getenv('TRADOVATE_STOPLOSS_T....')`

3. Calls `print(...)` for its side effect.

4. `try` block with 1 `except` clause.

Code (copy-paste safe)

```
def _setup_atm(self, tp=None, sl=None):

```

Place a market order with enhanced crash detection and recovery

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **raise** — Raises an exception explicitly. Either signals an invalid argument the caller should fix, or re-raises after logging.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **with self.lock:** enters a context manager.

Code (copy-paste safe)

```
def _place_order_side(self, symbol, qty, side, tp=None, sl=None, on_click=None, skip_positions_refresh=False,

    self._block_stats_fetching(False)

```

Method: TradovateAccount._block_stats_fetching

```

def _block_stats_fetching(self, block=True)

    Set a flag to block stats fetching during order placement.

```

Step by step (top-level body)

1. Assigns self._placing_order = block.

Code (copy-paste safe)

```

def _block_stats_fetching(self, block=True):
    """Set a flag to block stats fetching during order placement."""
    self._placing_order = block

```

Method: TradovateAccount._select_symbol

```

def _select_symbol(self, symbol)

```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **raise** — Raises an exception explicitly. Either signals an invalid argument the caller should fix, or re-raises after logging.

Step by step (top-level body)

1. Calls print(...) for its side effect.
2. Calls self._wait_for_no_overlay(...) for its side effect.
3. **try** block with 1 **except** clause.
4. Assigns max_attempts = 5.
5. **for** attempt in range(max_attempts): iterates.
6. Calls self._wait_for_no_overlay(...) for its side effect.

Code (copy-paste safe)

```

def _select_symbol(self, symbol):
    print(f"Selecting symbol: {symbol}")
    self._wait_for_no_overlay()

    # SPEED OPTIMIZATION: Try direct symbol selection first (for fast manual trading)

```

Method: TradovateAccount._api_fetch

```
def _api_fetch(self, endpoint, method='GET', body=None)
```

Execute a fetch() call in the browser against the Tradovate REST API. Returns parsed JSON data or None on failure.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns `body_js = f'opts.body = JSON.stringify({json.dumps(body)});' if bod....`
2. Assigns `js = f"\n var cb = arguments[arguments.length - 1];\n ....`
3. `try` block with 1 **except** clause.

Code (copy-paste safe)

```
def _api_fetch(self, endpoint, method="GET", body=None):
    """Execute a fetch() call in the browser against the Tradovate REST API.
    Returns parsed JSON data or None on failure."""
    body_js = f'opts.body = JSON.stringify({json.dumps(body)});' if body else ""
    js = f"""
    var cb = arguments[arguments.length - 1];
    (async function() {{
        try {{
            var auth = JSON.parse(sessionStorage.getItem('api_authenticator_state') || '{}');
            var token = auth.token || '';
            var env = auth.environment || 'demo';
            var base = 'https://' + env + '.tradovateapi.com/v1';
            var opts = {{
                method: '{method}',
                headers: {{
                    'Authorization': 'Bearer ' + token,
                    'Content-Type': 'application/json',
                    'Accept': 'application/json'
                }}
            }};
            {{body_js}}
            var r = await fetch(base + '{endpoint}', opts);
            var txt = await r.text();
            var d = null;
            try {{ d = JSON.parse(txt); }} catch(e) {{}}
            cb({{ok: r.ok, status: r.status, data: d}});
        }} catch(e) {{
            cb({{ok: false, error: e.toString()}});
        }}
    }})();

```

Method: `TradovateAccount._get_account_for_api`

```
def _get_account_for_api(self)
```

Get the first account id and name for API order placement.

Why these Python concepts were used

- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.

Step by step (top-level body)

1. Assigns `accounts = self._api_fetch('/account/list')`.
2. **if** not `accounts` or not `isinstance(accounts, list)` or `len(accounts) == 0`: branches conditionally.
3. Assigns `acct = accounts[0]`.
4. **return** (`acct['id'], acct.get('name', '?')`).

Code (copy-paste safe)

```
def _get_account_for_api(self):
    """Get the first account id and name for API order placement."""
    accounts = self._api_fetch("/account/list")
    if not accounts or not isinstance(accounts, list) or len(accounts) == 0:
        return None, None
    acct = accounts[0]
    return acct['id'], acct.get('name', '?')
```

Method: TradovateAccount.get_min_equity

```
def get_min_equity(self, account_id=None)
```

Get the minimum equity (drawdown limit) for an account via the API. Uses /cashBalance/getCashBalanceSnapshot for current net liq, /userAccountAutoLiq/deps for trailing drawdown limits, and /accountRiskStatus/list for the max net liq (trailing reference). Returns: dict with 'net_liq', 'min_equity', 'drawdown_remaining' or None on failure.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def get_min_equity(self, account_id=None):
    """Get the minimum equity (drawdown limit) for an account via the API.

def _place_brackets_post_fill(self, account_name, account_id, contract_name, qty, side, fill_price, tp, sl, tick_size):

```

Place TP and SL bracket orders after a market order has filled. For BUY main order: TP = Sell Limit (above fill), SL = Sell Stop (below fill) For SELL main order: TP = Buy Limit (below fill), SL = Buy Stop (above fill)

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns `tp_price = self._resolve_bracket_price(tp, tick_size, fill_price, si....`
2. Assigns `sl_price = self._resolve_bracket_price(sl, tick_size, fill_price, si....`
3. **if** `not tp_price` and `(not sl_price)`: branches conditionally.
4. **if** `side == 'Buy'`: branches conditionally (with an **else/elif** arm).
5. Calls `print(...)` for its side effect.
6. **if** `tp_price`: branches conditionally.
7. **if** `sl_price`: branches conditionally.

Code (copy-paste safe)

```
def _place_brackets_post_fill(self, account_name, account_id, contract_name,

    return cancelled

```

Method: TradovateAccount.get_orders_api

```
def get_orders_api(self)
```

Get current working orders via the REST API.

Step by step (top-level body)

1. **return** self._api_fetch('/order/list') or [].

Code (copy-paste safe)

```

def get_orders_api(self):
    """Get current working orders via the REST API."""
    return self._api_fetch("/order/list") or []

```

Method: TradovateAccount.get_trade_history

```
def get_trade_history(self)
```

*Get full trade history for ALL accounts under this login. Returns list of dicts, one per account:
 account_name, account_id, environment, balance, balance_sod, realized_pnl, open_pnl,
 trailing_max_drawdown, trailing_max_drawdown_limit, drawdown_mode, daily_pnl, fills*

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression ([f(x) for x in xs]). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. try block with 1 except clause.

Code (copy-paste safe)

```

```

Method: TradovateAccount.get_mnq_daily_pnl

```
def get_mnq_daily_pnl(self)
```

Get daily P&L for days with MNQ trading activity (farming days). Identifies farming days by checking for MNQ contract fills, then pulls the daily P&L from cashBalanceLog for those dates. Returns list of dicts, one per account that has MNQ activity: [{"account_name": str, "account_id": int, "mnq_daily_pnl": [{"date": "YYYY-MM-DD", "net_pnl": float}, ...]}

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **set comprehension** — Builds a set in one expression — usually to deduplicate the result of a transform.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

Step 8.5 — Build trader_companion/prop_firm_manager.py

What to do. Create the file `trader_companion/prop_firm_manager.py` in your project root and paste in the code shown in this step. The file is **2124** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

What this file is for. Coordinates the per-firm scraper instances, normalises their outputs, and pushes account state to the dashboard.

trader_companion/prop_firm_manager.py

2124 loc · 1 classes · 0 functions · 3 imports

Coordinates the per-firm scraper instances, normalises their outputs, and pushes account state to the dashboard. It defines **1** class, across **2,124** lines.

Python concepts demonstrated in this module

- Classes and objects
- Comprehensions
- Dunder methods
- f-strings
- Type hints

Imports — what each one is for

`import logging`

Why imported. Structured, levelled logging. Replaces `print()` with filterable, formattable output that can route to files, stderr, syslog, or HTTP endpoints.

Used in this file. `logging.getLogger`

Example. `logging.getLogger(__name__).info('connected to %s', host)`

Other common scenarios.

- `.debug()` / `.info()` / `.warning()` / `.error()` / `.exception()`
- `logger.exception()` captures the current traceback automatically
- `logging.basicConfig(level=logging.INFO)` for quick setup

- Handlers and Formatters route logs to files / streams / syslog

```
import datetime
```

Why imported. Dates, times, durations. The fundamental temporal types: date, time, datetime, timedelta, timezone.

Used in this file. datetime.date, datetime.date.today

Example. datetime.now() - timedelta(days=7) # one week ago

Other common scenarios.

- datetime.strptime(s, '%Y-%m-%d') parses a string
- datetime.strftime(fmt) formats one
- datetime.fromtimestamp(n) converts a Unix epoch
- datetime.utcnow() for UTC (better: datetime.now(timezone.utc))

```
from typing import Dict
from typing import Optional
from typing import Tuple
```

Why imported. Type-hint primitives — generics, unions, Optional, Callable, Protocol, TypeVar, TypedDict.

Used in this file. Dict, Optional, Tuple

Example. def lookup(k: str) -> Optional[int]: ...

Other common scenarios.

- List[int] / Dict[str, Any] / Tuple[int, str] (or bare list[int]+ on 3.9+)
- Callable[[int, int], int] for function signatures
- Protocol for structural typing (duck typing with checks)
- TypeVar('T') for generic functions and classes

Classes

```

```

Method: PropFirmManager.__init__

```
def __init__(self)
```

Why these Python concepts were used

- `__init__` — The constructor. Runs after Python has allocated the instance; assigns starting attribute values to self.

Step by step (top-level body)

1. Assigns `self.logger = logging.getLogger(__name__)`.
2. Assigns `self.current_firm_code = 'MFFU_Flex'`.
3. Declares `self._account_direction_locks: Dict[str, Dict] = {}`.
4. Assigns `self.firm_blueprints = {'MFFU_Flex': {'name': 'MFFU_Flex', 'account_sizes': ['$5....`

Code (copy-paste safe)

```

def __init__(self):
    self.logger = logging.getLogger(__name__)
    self.current_firm_code = "MFFU_Flex" # Default prop firm

    # Per-account daily direction locks: {account_number: {"date": date, "direction": "BUY"/"SELL"}}
    self._account_direction_locks: Dict[str, Dict] = {}

```

```

Method: PropFirmManager.detect_prop_firm

```
def detect_prop_firm(self, username: str) -> Optional[str]
```

Detect prop firm based on username prefix. Returns None if unrecognized.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., username: str). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type -> Optional[str]. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.

Step by step (top-level body)

1. **if** not username or (isinstance(username, str) and len(username) < 4): branches conditionally.
2. Assigns prefix = username[:4].upper().
3. **if** prefix in self.firm_blueprints: branches conditionally.
4. **if** any((prefix.startswith(var) for var in ['APEX'])): branches conditionally (with an **else/elif** arm).
5. Calls self.logger.warning(...) for its side effect.
6. **return** None.

Code (copy-paste safe)

```

def detect_prop_firm(self, username: str) -> Optional[str]:
    """Detect prop firm based on username prefix. Returns None if unrecognized."""
    if not username or (isinstance(username, str) and len(username) < 4):
        self.logger.warning(f"Username too short: '{username}', cannot detect prop firm")
        return None

    prefix = username[:4].upper()

```

```

if prefix in self.firm_blueprints:
    self.logger.info(f"Detected prop firm '{prefix}' from username: '{username}'")
    return prefix

if any(prefix.startswith(var) for var in ["APEX"]):
    return "Apex"
elif any(prefix.startswith(var) for var in ["FTPR"]):
    return "FundingTicks"
elif any(prefix.startswith(var) for var in ["ELTD", "TDFU"]):
    return "Trade Day"
elif any(prefix.startswith(var) for var in ["FNFT", "FTFN"]):
    return "Funded Next"
elif any(prefix.startswith(var) for var in ["MFFU"]):
    return "MFFU"
elif any(prefix.startswith(var) for var in ["V2-"]):
    return "TopStep"
elif any(prefix.startswith(var) for var in ["TDFY", "FTDF"]):
    return "Tradeify"
elif any(prefix.startswith(var) for var in ["LFE0", "LFF0"]):
    return "Lucid"
elif any(prefix.startswith(var) for var in ["AFAD"]):
    return "AlphaFutures"

self.logger.warning(f"Unknown prefix '{prefix}' from account '{username}' – prop firm not recognized")
return None

```

Method: PropFirmManager.get_firm_info

```
def get_firm_info(self, firm_code: str) -> Dict
```

Get complete prop firm information.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `firm_code: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> Dict`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. Assigns `normalized_code = firm_code`.
2. **if** `firm_code == 'Alpha Futures'`: branches conditionally (with an **else/elif** arm).
3. **return** `self.firm_blueprints.get(normalized_code, self.firm_blueprints['MFF....`

Code (copy-paste safe)

```

def get_firm_info(self, firm_code: str) -> Dict:
    """Get complete prop firm information."""
    # Normalize firm_code to handle variations
    normalized_code = firm_code
    if firm_code == "Alpha Futures":
        normalized_code = "AlphaFutures"
    elif firm_code == "FundedNext":
        normalized_code = "Funded Next"
    elif firm_code == "TopOneFutures":
        normalized_code = "Top One Futures"

```

```

elif firm_code in ("MFFU", "My Funded Futures"):
    # Legacy alias – MFFU is no longer a separate blueprint
    normalized_code = "MFFU_Flex"

return self.firm_blueprints.get(normalized_code, self.firm_blueprints["MFFU_Flex"])

```

Method: PropFirmManager.get_account_sizes

```
def get_account_sizes(self, firm_code: str) -> list
```

Get account sizes for specific prop firm.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `firm_code: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> list`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. Assigns `firm_info = self.get_firm_info(firm_code)`.
2. **return** `firm_info.get('account_sizes', ['$50,000'])`.

Code (copy-paste safe)

```

def get_account_sizes(self, firm_code: str) -> list:
    """Get account sizes for specific prop firm."""
    firm_info = self.get_firm_info(firm_code)
    return firm_info.get("account_sizes", ["$50,000"])

```

Method: PropFirmManager.get_trading_phases

```
def get_trading_phases(self, firm_code: str) -> list
```

Get trading phases for specific prop firm.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `firm_code: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> list`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. Assigns `firm_info = self.get_firm_info(firm_code)`.
2. **return** `firm_info.get('trading_phases', ['Challenge Phase', 'Funded Phase'], ...)`

Code (copy-paste safe)

```

def get_trading_phases(self, firm_code: str) -> list:
    """Get trading phases for specific prop firm."""
    firm_info = self.get_firm_info(firm_code)

```

```
return firm_info.get("trading_phases", ["Challenge Phase", "Funded Phase", "Farming Phase"])
```

Method: PropFirmManager.convert_account_size_to_key

```
def convert_account_size_to_key(self, account_size: str, firm_code: str=None) -> str
```

Convert account size string to size key (e.g., '\$50,000' -> '50k')

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `account_size: str`, `firm_code: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> str`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. **if not** `account_size`: branches conditionally.
2. Assigns `s = account_size.lower().replace(',', '').replace('$', '').strip()`.
3. **if** `'150' in s` or `s == '150k'`: branches conditionally.
4. **if** `'100' in s` or `s == '100k'`: branches conditionally.
5. **return** `'50k'`.

Code (copy-paste safe)

```
def convert_account_size_to_key(self, account_size: str, firm_code: str = None) -> str:
    """Convert account size string to size key (e.g., '$50,000' -> '50k')"""
    if not account_size:
        return "50k"
    s = account_size.lower().replace(",", "").replace("$", "").strip()
    if "150" in s or s == "150k":
        return "150k"
    if "100" in s or s == "100k":
        return "100k"
    return "50k"
```

Method: PropFirmManager.get_strategy_config

```
def get_strategy_config(self, firm_code: str, phase_key: str, size_key: str='50k') -> Dict
```

Get strategy configuration for specific prop firm and phase.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `firm_code: str`, `phase_key: str`, `size_key: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> Dict`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns `size_key = self.convert_account_size_to_key(size_key, firm_code)`.
2. Calls `self.logger.info(...)` for its side effect.
3. Assigns `firm_info = self.get_firm_info(firm_code)`.
4. Assigns `strategy_configs = firm_info.get('strategy_configs', {})`.
5. Assigns `phase_config = strategy_configs.get(phase_key, {})`.
6. `if not phase_config:` branches conditionally.
7. Calls `self.logger.info(...)` for its side effect.
8. Assigns `config = phase_config.get(size_key)`.
9. `if not config:` branches conditionally (with an **else/elif** arm).
10. `if config:` branches conditionally.
11. **return** config.

Code (copy-paste safe)

```
def get_strategy_config(self, firm_code: str, phase_key: str, size_key: str = "50k") -> Dict:
    """Get strategy configuration for specific prop firm and phase."""
    # Normalize size_key: "$50,000" -> "50k", "$100,000" -> "100k", etc.
    size_key = self.convert_account_size_to_key(size_key, firm_code)
    self.logger.info(
        f"[DEBUG get_strategy_config] firm_code='{firm_code}', phase_key='{phase_key}', size_key='{size_key}'")

        config['mt5_volume'] = round(config['mt5_volume'], 2)

return config

```

Method: PropFirmManager.validate_firm_setup

```
def validate_firm_setup(self, username: str) -> Tuple[Optional[str], Dict]
```

Validate and get complete prop firm setup for a username.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `username: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> Tuple[Optional[str], Dict]`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `firm_code = self.detect_prop_firm(username)`.
2. **if** `firm_code` is `None`: branches conditionally.
3. Assigns `firm_info = self.get_firm_info(firm_code)`.
4. Calls `self.logger.info(...)` for its side effect.
5. **return** (`firm_code`, `firm_info`).

Code (copy-paste safe)

```

def validate_firm_setup(self, username: str) -> Tuple[Optional[str], Dict]:
    """Validate and get complete prop firm setup for a username."""
    firm_code = self.detect_prop_firm(username)
    if firm_code is None:

return config

```

Method: PropFirmManager.get_prop_firm_account_sizes

```
def get_prop_firm_account_sizes(self, firm_code=None)
```

Get account sizes for detected or specified prop firm

Step by step (top-level body)

1. if `firm_code` is `None`: branches conditionally.

2. **return** self.get_account_sizes(firm_code).

Code (copy-paste safe)

```
def get_prop_firm_account_sizes(self, firm_code=None):
    """Get account sizes for detected or specified prop firm"""
    if firm_code is None:
        firm_code = self.current_firm_code
    return self.get_account_sizes(firm_code)
```

Method: PropFirmManager.get_prop_firm_trading_phases

```
def get_prop_firm_trading_phases(self, firm_code=None)
```

Get trading phases for detected or specified prop firm

Step by step (top-level body)

1. **if** firm_code is None: branches conditionally.
2. **return** self.get_trading_phases(firm_code).

Code (copy-paste safe)

```
def get_prop_firm_trading_phases(self, firm_code=None):
    """Get trading phases for detected or specified prop firm"""
    if firm_code is None:

```

Method: PropFirmManager.format_volume_for_display

```
def format_volume_for_display(self, volume)
```

Format MT5 volume for display (used by GUI)

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **if** volume == 0: branches conditionally.
2. **return** f'{volume:.1f}'.

Code (copy-paste safe)

```
def format_volume_for_display(self, volume):
    """Format MT5 volume for display (used by GUI)"""
    if volume == 0:
        return "0.0"
    return f"{volume:.1f}"
```

Method: PropFirmManager.get_tick_value

```
def get_tick_value(self, symbol: str) -> float
```

Get tick value for a given trading symbol. Returns the dollar value per tick for the given contract symbol. This is the single source of truth for tick values across the app.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `symbol: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> float`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns `symbol_upper = symbol.upper()` if `symbol` else `""`.
2. **if** `'MGC'` in `symbol_upper`: branches conditionally.
3. **if** `'GC'` in `symbol_upper`: branches conditionally.
4. **if** `'MNQ'` in `symbol_upper`: branches conditionally.
5. **if** `'NQ'` in `symbol_upper`: branches conditionally.
6. **return** `0.5`.

Code (copy-paste safe)

```
def get_tick_value(self, symbol: str) -> float:
    """Get tick value for a given trading symbol.

    Returns the dollar value per tick for the given contract symbol.
    This is the single source of truth for tick values across the app.
    """
    symbol_upper = symbol.upper() if symbol else ""
    # Micro Gold contracts
    if "MGC" in symbol_upper:
        return 1.0
    # Standard Gold contracts
    if "GC" in symbol_upper:
        return 10.0
    # Micro NASDAQ contracts (check before standard NQ)
    if "MNQ" in symbol_upper:
        return 0.5
    # Standard NASDAQ contracts
    if "NQ" in symbol_upper:
        return 5.0
    # Default to micro contract value
    return 0.5
```

Method: `PropFirmManager.predict_next_trade`

```
def predict_next_trade(self, firm_code: str, current_phase: str, current_profit: float,
    size_key: str='50k') -> Dict
```

Predict current stage and next trade based on balance. Walks the ordered trade progression for the firm/phase, computing cumulative profit at each stage boundary. Returns a dict with: `current_stage` -

human label like "Challenge Trade 2" next_stage - human label for next trade, or "Phase Complete"
next_config - the blueprint config dict for the next trade (or None) next_phase_key - the blueprint key for
the next trade balance_target - the cumulative \$ target at end of current stage stages - list of (label,
phase_key, cumul_target) for all stages

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `firm_code: str`, `current_phase: str`, `current_profit: float`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> Dict`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns `phase_map = {'Challenge': 'Challenge', 'Funded': 'Funded', 'Farming':....`
2. Assigns `phase_key_group = phase_map.get(current_phase, current_phase)`.
3. Assigns `firm_orders = self._PHASE_TRADE_ORDER.get(firm_code, {})`.

return round(cumulative, 2)

```

Method: PropFirmManager.adjust_tp_sl_for_balance

```
def adjust_tp_sl_for_balance(self, config: Dict, current_profit: float) -> Dict
```

Adjust TP and SL ticks/points based on current account profit. If the account already has profit, TP is reduced so the trade doesn't overshoot the blueprint target. If the account has a loss, TP is increased to recover back to the target. SL is adjusted inversely. Returns a NEW config dict with adjusted values (original is not mutated).

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., config: Dict, current_profit: float). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type -> Dict. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Method: PropFirmManager.compute_account_status

```

def compute_account_status(self, firm_code: str, phase: str, current_balance: float,
    starting_balance: float=50000.0, breached: bool=False) -> str

```

Compute the account status based on balance vs profit targets. Returns one of: 'Pass', 'Fail', 'In Progress', or None if unable to determine. Parameters: firm_code: Canonical firm identifier (e.g. 'MFFU', 'TopStep') phase: Current phase display name ('Challenge' or 'Funded') current_balance: Live broker balance starting_balance: Account starting balance (default \$50,000) breached: Whether the prop firm reports the account as breached

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., firm_code: str, phase: str, current_balance: float). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type -> str. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **if** breached: branches conditionally.
2. Assigns targets = self._PROFIT_TARGETS.get(firm_code, {}).
3. Assigns phase_key = 'Challenge' if phase == 'Challenge' else 'Funded'.
4. Assigns target = targets.get(phase_key).
5. **if** target is None: branches conditionally.
6. Assigns profit = current_balance - starting_balance.
7. **if** profit >= target: branches conditionally.
8. **if** firm_code in ('MFFU', 'MFFU_Flex', 'My Funded Futures'): branches conditionally (with an **else/elif** arm).
9. **if** current_balance <= hard_stop: branches conditionally.
10. **return** 'In Progress'.

```

Method: PropFirmManager.adjust_farming_tp_sl

```
def adjust_farming_tp_sl(self, config: Dict, current_balance: float, firm_code: str) -> Dict
```

Adjust MT5 TP for farming trades based on hard-stop proximity. Farming trades use micro contracts (MNQM6). If the MT5 TP is so large that the prop account would breach the hard-stop threshold before MT5 closes, we cap MT5 TP to a safe distance. Only MT5 TP is adjusted — Tradovate TP/SL and MT5 SL stay unchanged. Returns a NEW config dict (original is not mutated).

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., config: Dict, current_balance: float, firm_code: str). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type -> Dict. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

    return lock["direction"]
return None

```

Method: PropFirmManager.reset_direction_lock

```
def reset_direction_lock(self, account_number: str) -> None
```

Manually reset the direction lock for a specific account.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `account_number: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> None`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Calls `self._account_direction_locks.pop(...)` for its side effect.
2. Calls `self.logger.info(...)` for its side effect.

Code (copy-paste safe)

```

def reset_direction_lock(self, account_number: str) -> None:
    """Manually reset the direction lock for a specific account."""
    self._account_direction_locks.pop(account_number, None)
    self.logger.info(f"[RULE] Direction lock reset for account {account_number}")

```

Method: PropFirmManager.detect_firm_from_account

```
def detect_firm_from_account(self, account_number: str) -> Optional[str]
```

Detect the prop firm from a Tradovate/TopStep account number. Returns the UI-facing blueprint name (e.g. 'MFFU_Flex', 'Funded Next') or None if detection fails.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `account_number: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> Optional[str]`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `detected_code = self.detect_prop_firm(account_number)`.
2. **if** `detected_code` is `None`: branches conditionally.

3. Assigns `blueprint = self.DETECTED_TO_BLUEPRINT.get(detected_code)`.

4. `if blueprint`: branches conditionally (with an `else/elif` arm).

5. `return blueprint`.

Code (copy-paste safe)

```
def detect_firm_from_account(self, account_number: str) -> Optional[str]:
    """Detect the prop firm from a Tradovate/TopStep account number.

    Returns the UI-facing blueprint name (e.g. 'MFFU_Flex', 'Funded Next')
    or None if detection fails.
    """
    detected_code = self.detect_prop_firm(account_number)
    if detected_code is None:
        self.logger.warning(f"Account '{account_number}' – prop firm could not be identified")

    else:
        self.logger.warning(
            f"Account '{account_number}' detected as '{detected_code}' but no blueprint mapping exists")
    return blueprint
```

Method: `PropFirmManager.validate_blueprint_match`

```
def validate_blueprint_match(self, account_number: str, selected_blueprint: str) -> Tuple[bool, Optional[str]]:
```

Check whether the selected blueprint matches the connected account. Args: `account_number`: Account identifier from Tradovate/TopStep. `selected_blueprint`: The blueprint currently selected in the UI. Returns: (`is_match`, `detected_blueprint`) - `is_match` is True when they are compatible. - `detected_blueprint` is the blueprint we think the account belongs to.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `account_number: str`, `selected_blueprint: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> Tuple[bool, Optional[str]]`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `detected = self.detect_firm_from_account(account_number)`.

2. `if detected is None`: branches conditionally.

3. Assigns `compatible_groups = [{'MFFU', 'MFFU_Flex'}, {'Alpha Futures', 'AlphaFutures G...}]`.

4. `for group in compatible_groups`: iterates.

5. Assigns `is_match = detected == selected_blueprint`.

6. `if not is_match`: branches conditionally.

7. `return (is_match, detected)`.

Code (copy-paste safe)

```
def validate_blueprint_match(self, account_number: str, selected_blueprint: str) -> Tuple[bool, Optional[str]]:
    """Check whether the selected blueprint matches the connected account.

    Args:
        account_number: Account identifier from Tradovate/TopStep.
        selected_blueprint: The blueprint currently selected in the UI.

    Returns:
        (is_match, detected_blueprint)
        - is_match is True when they are compatible.
        - detected_blueprint is the blueprint we think the account belongs to.
    """
    detected = self.detect_firm_from_account(account_number)
    if detected is None:
        # Detection inconclusive – allow but warn
        return True, None

    # Treat MFFU and MFFU_Flex as compatible
    compatible_groups = [
        {"MFFU", "MFFU_Flex"},
        {"Alpha Futures", "AlphaFutures GC"},
    ]
    for group in compatible_groups:
        if detected in group and selected_blueprint in group:
            return True, detected

    is_match = (detected == selected_blueprint)
    if not is_match:
        self.logger.warning(
            f"Blueprint MISMATCH: account '{account_number}' belongs to '{detected}' "
            f"but '{selected_blueprint}' is selected"
        )
    return is_match, detected
```

Checkpoint — what works now. The scrapers can log into each prop firm and read account state. Run any of them in isolation and watch a Chrome window open, log in, and navigate to the dashboard page. The data they extract is still in-memory only — it will be pushed to the server in the next phase.

Chapter 9 — Phase 7 — Pushing data to the dashboard

The desktop companion runs on the trader's machine. The web dashboard runs on a server. They communicate through an HTTP ingestion API. In this phase we build the outbound HTTP client and the periodic sync that pushes MT5 deal history to the server.

Files we build in this phase, in order:

- `trader_companion/push_data.py`
- `trader_companion/mt5_dashboard_sync.py`

Python concepts you'll meet in this phase

- f-strings (2) · Exceptions (2) · Dunder methods (1) · Classes and objects (1) · Module-level state (1) · Comprehensions (1)

Each is explained in Chapter 2 (the primer). The number in parentheses is how many of this phase's files use that concept.

Step 9.1 — Build `trader_companion/push_data.py`

What to do. Create the file `trader_companion/push_data.py` in your project root and paste in the code shown in this step. The file is **194** lines long; we walk through it piece by piece below.

Depends on. This file imports from internal modules built in earlier steps: `trader_companion`. If any of those imports fail, jump back to the step that introduced them.

What this file is for. Outbound HTTP client for the dashboard's ingestion API.

`trader_companion/push_data.py`

194 loc · 0 classes · 4 functions · 7 imports

Outbound HTTP client for the dashboard's ingestion API. It defines **4** module-level functions, across **194** lines. Module docstring: *MT5 Data Pusher - Command Line Interface*

Module docstring

MT5 Data Pusher - Command Line Interface Simple script for traders to push data to the dashboard from command line. NO API KEY REQUIRED - just your email address!

Python concepts demonstrated in this module

- Exceptions · f-strings

Imports — what each one is for

```
import sys
```

Why imported. Access to the running interpreter — argv, stdin/stdout, exit codes, the import search path, and the platform name.

Used in this file. sys.exit, sys.path, sys.path.insert

Example. sys.exit(1) # terminate the process with a non-zero status

Other common scenarios.

- sys.argv[1:] reads the command-line arguments
- sys.path.insert(0, 'extra') prepends to the import search path
- sys.stderr.write(msg) writes to standard error
- sys.platform tells you 'win32', 'linux', or 'darwin'
- sys.modules is the global cache of already-imported modules

```
import os
```

Why imported. Operating-system interface. Path manipulation, environment variables, working-directory operations, exit codes, and thin wrappers around POSIX/Windows syscalls.

Used in this file. os.path, os.path.abspath, os.path.dirname

Example. os.path.join(root, 'subdir', 'file.txt') # joins with the OS-correct separator

Other common scenarios.

- os.environ.get('API_KEY') to read environment variables
- os.makedirs(path, exist_ok=True) to create nested directories
- os.listdir(path) to list a directory's contents
- os.remove(path) / os.rename(src, dst) to delete or move a file
- os.getcwd() / os.chdir(path) to inspect or change the working dir

```
import json
```

Why imported. JSON encoding and decoding — the standard wire format for config files, API payloads, and inter-process messages.

Used in this file. json.dumps

Example. json.loads(response.text) # parse a JSON string to dict

Other common scenarios.

- json.dumps(obj, indent=2) for pretty-printing
- json.dump(obj, file) / json.load(file) for file I/O
- default=str handles non-serialisable types like datetime
- object_hook= customises decoding (e.g., to dataclass instances)

```
import gzip as _gzip
```

Why imported. Read/write gzip-compressed streams.

Used in this file. `_gzip.compress`

Example. with `gzip.open('logs.gz', 'rt')` as `f`: ...

Other common scenarios.

- `gzip.compress(b)` / `gzip.decompress(b)` for in-memory blobs
- Pair with `shutil.copyfileobj` for streaming compression

```
import argparse
```

Why imported. Command-line argument parsing. Generates `--help`, type-coerces values, and dispatches sub-commands.

Used in this file. `argparse.ArgumentParser`

Example. `parser.add_argument('--verbose', action='store_true')`

Other common scenarios.

- `type=int` / `type=Path` coerces the value
- subparsers for git-style sub-commands
- `ArgumentDefaultsHelpFormatter` shows defaults in `--help`

```
import requests
```

Why imported. The de-facto Python HTTP client. Synchronous; trades raw speed for an extremely friendly API.

Used in this file. `requests.post`

Example. `requests.get(url, timeout=10).json()`

Other common scenarios.

- `Session()` reuses TCP connections across calls
- `params=`, `headers=`, `json=`, `data=` for query/body shapes
- `raise_for_status()` turns 4xx/5xx into an exception
- `stream=True` for large downloads

```
from trader_companion.trader_app import MT5DataPusher
```

Why imported. Internal package — the desktop trader companion. See chapter on `trader_companion/`.

Used in this file. `MT5DataPusher`

Functions

```
def lookup_client(url, email)
```

Lookup client hierarchy from email - NO API KEY.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't

have to handle it.

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def lookup_client(url, email):
    """Lookup client hierarchy from email - NO API KEY."""
    try:
        response = requests.post(
            f"{url.rstrip('/')}/api/client/auth",
            json={"email": email},
            headers={"Content-Type": "application/json"},
            timeout=15
        )

        if response.status_code == 200:
            data = response.json()
            if data.get("status") == "success":
                return data.get("identity", {}), None
            else:
                return None, data.get("message", "Client not found")
        else:
            return None, f"API Error: {response.status_code}"
    except Exception as e:
        return None, str(e)
```

```
def push_data(url, email, account, positions, deals, statistics)
```

Push data to dashboard - NO API KEY. Sends gzip-compressed JSON.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def push_data(url, email, account, positions, deals, statistics):
    """Push data to dashboard - NO API KEY. Sends gzip-compressed JSON."""
    try:
        payload = {
            "email": email,
            "account": account,
            "positions": positions,
            "deals": deals,
            "statistics": statistics,
```

```

        "evaluations": [],
        "dropdown_options": {}
    }
    raw = json.dumps(payload).encode('utf-8')
    compressed = _gzip.compress(raw, compresslevel=6)
    response = requests.post(
        f"{url.rstrip('/')}/api/client/push",
        data=compressed,
        headers={"Content-Type": "application/json", "Content-Encoding": "gzip"},
        timeout=30
    )

    if response.status_code == 200:
        data = response.json()
        if data.get("status") == "success":
            return True, data.get("message", "Data pushed successfully")
        else:
            return False, data.get("message", "Push failed")
    else:
        return False, f"HTTP {response.status_code}"
except Exception as e:
    return False, str(e)

```

```
def migrate_sheet(url, email, sheet_url)
```

Migrate data from Google Sheets.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

def migrate_sheet(url, email, sheet_url):
    """Migrate data from Google Sheets."""
    try:
        response = requests.post(
            f"{url.rstrip('/')}/api/client/migrate_sheet",
            json={"email": email, "sheet_url": sheet_url},
            headers={"Content-Type": "application/json"},
            timeout=60
        )

        if response.status_code == 200:
            data = response.json()
            if data.get("status") == "success":
                return True, f"Imported {data.get('records_imported', 0)} records"
            else:
                return False, data.get("message", "Migration failed")
        else:
            return False, f"HTTP {response.status_code}"
    
```

```
except Exception as e:
    return False, str(e)
```

```
def main()
```

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `parser = argparse.ArgumentParser(description='Push MT5 data to Tra....`
2. Calls `parser.add_argument(...)` for its side effect.
3. Calls `parser.add_argument(...)` for its side effect.
4. Calls `parser.add_argument(...)` for its side effect.
5. Calls `parser.add_argument(...)` for its side effect.
6. Calls `parser.add_argument(...)` for its side effect.
7. Calls `parser.add_argument(...)` for its side effect.
8. Calls `parser.add_argument(...)` for its side effect.
9. Assigns `args = parser.parse_args()`.
10. Calls `print(...)` for its side effect.
11. Calls `print(...)` for its side effect.
12. Calls `print(...)` for its side effect.
13. Calls `print(...)` for its side effect.
14. Assigns `(client_info, error) = lookup_client(args.url, args.email)`.
15. ... and 22 more statement(s) in the body.

Code (copy-paste safe)

```
def main():
    parser = argparse.ArgumentParser(description='Push MT5 data to Trading Dashboard (No API Key Required)')
    parser.add_argument('--url', default='https://www.tradeopss.com', help='Dashboard URL')
    parser.add_argument('--email', required=True, help='Your registered client email')
    parser.add_argument('--sheet', help='Google Sheet URL to migrate data from')
    parser.add_argument('--mt5-login', help='MT5 account login')
    parser.add_argument('--mt5-password', help='MT5 account password')
    parser.add_argument('--mt5-server', help='MT5 server name')
    parser.add_argument('--days', type=int, default=30, help='Days of history to fetch')

print("\n[*] Done!")

```

Step 9.2 — Build trader_companion/mt5_dashboard_sync.py

What to do. Create the file `trader_companion/mt5_dashboard_sync.py` in your project root and paste in the code shown in this step. The file is **840** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

What this file is for. Periodically pushes the local MT5 deal history to the dashboard's database.

trader_companion/mt5_dashboard_sync.py

840 loc · 1 classes · 1 functions · 5 imports

Periodically pushes the local MT5 deal history to the dashboard's database. It defines **1** class and **1** module-level function, across **840** lines. Module docstring: *MT5 Dashboard Sync Service*

Module docstring

MT5 Dashboard Sync Service Syncs MT5 trading history to the TradeConnector Dashboard

Python concepts demonstrated in this module

- Classes and objects
- Comprehensions
- Dunder methods
- Exceptions
- f-strings

Module-level state

Imports — what each one is for

```
import MetaTrader5 as mt5
```

Why imported. Official MetaQuotes Python API for MT5. Connects to a local terminal, places orders, reads tick/bar history.

Used in this file. mt5.DEAL_ENTRY_IN, mt5.DEAL_ENTRY_OUT, mt5.DEAL_TYPE_BUY, mt5.DEAL_TYPE_SELL, mt5.account_info, mt5.history_deals_get, mt5.initialize, mt5.last_error

Example. mt5.initialize(); mt5.order_send(request)

Other common scenarios.

- mt5.symbols_get() / mt5.symbol_info(symbol)
- mt5.history_deals_get(from_, to_) returns closed deals
- mt5.account_info() returns balance/equity/currency
- Always mt5.shutdown() in a finally to release the terminal

```
import requests
```

Why imported. The de-facto Python HTTP client. Synchronous; trades raw speed for an extremely friendly API.

Used in this file. requests.exceptions, requests.exceptions.ConnectionError, requests.exceptions.Timeout, requests.get, requests.post

Example. requests.get(url, timeout=10).json()

Other common scenarios.

- Session() reuses TCP connections across calls
- params=, headers=, json=, data= for query/body shapes
- raise_for_status() turns 4xx/5xx into an exception
- stream=True for large downloads

```
import logging
```

Why imported. Structured, levelled logging. Replaces print() with filterable, formattable output that can route to files, stderr, syslog, or HTTP endpoints.

Used in this file. logging.error, logging.info, logging.warning

Example. logging.getLogger(__name__).info('connected to %s', host)

Other common scenarios.

- .debug() / .info() / .warning() / .error() / .exception()
- logger.exception() captures the current traceback automatically
- logging.basicConfig(level=logging.INFO) for quick setup
- Handlers and Formatters route logs to files / streams / syslog

```
from datetime import datetime
from datetime import timedelta
```

Why imported. Dates, times, durations. The fundamental temporal types: date, time, datetime, timedelta, timezone.

Used in this file. datetime, timedelta

Example. datetime.now() - timedelta(days=7) # one week ago

Other common scenarios.

- `datetime.strptime(s, '%Y-%m-%d')` parses a string
- `datetime.strftime(fmt)` formats one
- `datetime.fromtimestamp(n)` converts a Unix epoch
- `datetime.utcnow()` for UTC (better: `datetime.now(timezone.utc)`)

`import json`

Why imported. JSON encoding and decoding — the standard wire format for config files, API payloads, and inter-process messages.

Used in this file. *No direct attribute access detected — likely imported for side effects, re-export, or string references.*

Example. `json.loads(response.text)` # parse a JSON string to dict

Other common scenarios.

- `json.dumps(obj, indent=2)` for pretty-printing
- `json.dump(obj, file)` / `json.load(file)` for file I/O
- `default=str` handles non-serialisable types like `datetime`
- `object_hook=` customises decoding (e.g., to `dataclass` instances)

Classes

```
class MT5DashboardSync
```

Code (copy-paste safe)

```
class MT5DashboardSync:
    def __init__(self, dashboard_url="http://localhost:5000/api", user_email=None):
        """
        Initialize MT5 Dashboard Sync

        Args:
            dashboard_url: Base URL for dashboard API
            user_email: User email for authentication
        """
        self.dashboard_url = dashboard_url.rstrip('/')
        self.user_email = user_email
        self.auth_token = None

```

Method: MT5DashboardSync.__init__

```
def __init__(self, dashboard_url='http://localhost:5000/api', user_email=None)
```

Initialize MT5 Dashboard Sync Args: dashboard_url: Base URL for dashboard API user_email: User email for authentication

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **__init__** — The constructor. Runs after Python has allocated the instance; assigns starting attribute values to self.

Step by step (top-level body)

1. Assigns `self.dashboard_url = dashboard_url.rstrip('/')`.
2. Assigns `self.user_email = user_email`.
3. Assigns `self.auth_token = None`.
4. Assigns `self._is_connected = False`.
5. Calls `logging.info(...)` for its side effect.

Code (copy-paste safe)

```

def __init__(self, dashboard_url="http://localhost:5000/api", user_email=None):
    """
    Initialize MT5 Dashboard Sync

    Args:
        dashboard_url: Base URL for dashboard API
        user_email: User email for authentication
    """
    self.dashboard_url = dashboard_url.rstrip('/')

```

```

self.user_email = user_email
self.auth_token = None
self._is_connected = False
logging.info(f"[MT5 SYNC] Initialized for email: {user_email}")

```

Method: MT5DashboardSync.set_auth_token

```

def set_auth_token(self, token)

    Set authentication token from dashboard login

```

Step by step (top-level body)

1. Assigns `self.auth_token = token`.
2. Calls `logging.info(...)` for its side effect.

Code (copy-paste safe)

```

def set_auth_token(self, token):
    """Set authentication token from dashboard login"""
    self.auth_token = token
    logging.info("[MT5 SYNC] Authentication token set")

```

Method: MT5DashboardSync.check_dashboard_health

```

def check_dashboard_health(self)

    Check if dashboard backend is running and healthy Returns: dict: {'connected': bool, 'status': str, 'message': str}

```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 3 **except** clauses.

Code (copy-paste safe)

```

def check_dashboard_health(self):
    """
    Check if dashboard backend is running and healthy

    Returns:
        dict: {'connected': bool, 'status': str, 'message': str}
    """
    try:
        # Check backend health endpoint
        backend_url = self.dashboard_url.replace('/api', '')
        health_url = f"{backend_url}/health"

        response = requests.get(health_url, timeout=3)

```

```

Method: MT5DashboardSync._extract_account_from_comment

```
def _extract_account_from_comment(self, comment)
```

Extract account number and prop firm from MT5 comment Supported formats: - TopStep: 'PA-TS123456', 'TS123456', 'PA123456', or variations - Tradovate: 'TRDV123456', 'TV123456', or variations - Generic: Treats any alphanumeric string as account number - Empty: Returns empty account number (trade will be skipped) - With Phase: 'ACCOUNT_CH1', 'ACCOUNT_FD1', etc. (phase suffix is stripped) Returns: dict: {'accountNumber': str, 'propFirm': str}

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.

Step by step (top-level body)

1. **if** not comment or not comment.strip(): branches conditionally.
2. Assigns comment = comment.strip().
3. Imports re (lazy import inside the function).
4. **if** '_' in comment: branches conditionally.
5. Assigns clean_comment = comment.replace('#', "").replace('/', "").strip().
6. **try** block with 1 **except** clause.
7. **if** any((keyword in clean_comment.upper() for keyword in ['TS', 'TOPSTE...: branches conditionally.
8. **if** any((keyword in clean_comment.upper() for keyword in ['TRDV', 'TV',...: branches conditionally.
9. **if** clean_comment and len(clean_comment) >= 3: branches conditionally.
10. **return** {'accountNumber': "", 'propFirm': 'Unknown'}.

Code (copy-paste safe)

```

```

Method: MT5DashboardSync.auto_discover_and_sync

```
def auto_discover_and_sync(self)
```

Automatically discover all prop firm accounts from MT5 and sync to dashboard. Process: 1. Fetch all MT5 trades 2. Extract unique account numbers from comments 3. Group trades by account and lot size to determine phase 4. Auto-create/update accounts in dashboard 5. Sync all hedge results Returns: dict: Summary of discovery and sync results

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def auto_discover_and_sync(self):
    """

```

Method: MT5DashboardSync.sync_to_dashboard

```
def sync_to_dashboard(self, account_number=None, phase=None, prop_firm=None)
```

Extract Tradovate/TopStep account numbers and hedge amounts from MT5 trades MT5 is ONLY used to extract: 1. Prop firm account numbers from trade comments (Tradovate, TopStep) 2. Hedge amounts based on lot sizes 3. Trade P&L per hedge column MT5 account is NOT matched - just extract data and send to auto-discover. Use auto_discover_and_sync() instead for full automation. Args: account_number: Prop firm account number (optional) phase: Trading phase (optional) prop_firm: Prop firm name (optional) Returns: dict: Sync result (redirects to auto-discover)

Step by step (top-level body)

1. Calls logging.info(...) for its side effect.
2. return self.auto_discover_and_sync().

Code (copy-paste safe)

```
def sync_to_dashboard(self, account_number=None, phase=None, prop_firm=None):
    """
    Extract Tradovate/TopStep account numbers and hedge amounts from MT5 trades

    MT5 is ONLY used to extract:
    1. Prop firm account numbers from trade comments (Tradovate, TopStep)
    2. Hedge amounts based on lot sizes
    3. Trade P&L per hedge column

    MT5 account is NOT matched - just extract data and send to auto-discover.
    Use auto_discover_and_sync() instead for full automation.

    Args:
        account_number: Prop firm account number (optional)
        phase: Trading phase (optional)
        prop_firm: Prop firm name (optional)

    Returns:
        dict: Sync result (redirects to auto-discover)
    """
    logging.info("[MT5 SYNC] Redirecting to auto-discover for full account extraction...")
    return self.auto_discover_and_sync()
```

Method: MT5DashboardSync.get_sync_status

```
def get_sync_status(self, account_number)
```

Get sync status for an account Args: account_number: Prop firm account number Returns: dict: Sync status

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. try block with 1 except clause.

Code (copy-paste safe)

```
def get_sync_status(self, account_number):
    """
    Get sync status for an account

    Args:
        account_number: Prop firm account number

    Returns:
        dict: Sync status
    """
    try:
        if not self.auth_token:
            return {
                'success': False,
                'error': 'Not authenticated'
            }

        headers = {
            'Authorization': f'Bearer {self.auth_token}'
        }

        url = f"{self.dashboard_url}/mt5-sync/account/{account_number}"

        response = requests.get(url, headers=headers, timeout=10)

        if response.status_code == 200:
            return response.json()
        else:
            return {
                'success': False,
                'error': f'Status check failed: {response.status_code}'
            }

    except Exception as e:
        logging.error(f"[MT5 SYNC] Error checking sync status: {e}")
        return {
            'success': False,
            'error': str(e)
        }
```

Method: MT5DashboardSync.auto_sync_all_accounts

```
def auto_sync_all_accounts(self, accounts_config)
```

Automatically sync all configured accounts Args: accounts_config: List of account dictionaries with: - accountNumber - phase - propFirm Returns: dict: Summary of sync results

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns results = {'total': len(accounts_config), 'success': 0, 'failed': 0....

2. **for** account in accounts_config: iterates.

3. Calls logging.info(...) for its side effect.

4. **return** results.

Code (copy-paste safe)

```
def auto_sync_all_accounts(self, accounts_config):
    """
    Automatically sync all configured accounts

    Args:
        accounts_config: List of account dictionaries with:
            - accountNumber
            - phase
            - propFirm

    Returns:
        dict: Summary of sync results
    """
    results = {
        'total': len(accounts_config),
        'success': 0,
        'failed': 0,
        'details': []
    }

    for account in accounts_config:
        account_number = account.get('accountNumber')
        phase = account.get('phase')
        prop_firm = account.get('propFirm')

        logging.info(f"[MT5 SYNC] Auto-syncing account {account_number} ({phase})")

        result = self.sync_to_dashboard(account_number, phase, prop_firm)

        if result.get('success'):
            results['success'] += 1
        else:
            results['failed'] += 1

        results['details'].append({
            'accountNumber': account_number,
            'phase': phase,
            'result': result
        })

    logging.info(f"[MT5 SYNC] Auto-sync complete: {results['success']}/{results['total']} successful")

    return results
```

Functions

```
def get_mt5_sync(dashboard_url='http://localhost:5000/api', user_email=None)
```

Get or create global MT5 sync instance

Why these Python concepts were used

- **global** — Rebinds a module-level name from inside the function. A smell in larger codebases — usually means a singleton or cache that could be passed in instead.

Step by step (top-level body)

1. Declares globals: `_mt5_sync_instance`.
2. `if _mt5_sync_instance is None or _mt5_sync_instance.user_email != user...:` branches conditionally.
3. `return _mt5_sync_instance`.

Code (copy-paste safe)

```
def get_mt5_sync(dashboard_url="http://localhost:5000/api", user_email=None):
    """Get or create global MT5 sync instance"""
    global _mt5_sync_instance

    if _mt5_sync_instance is None or _mt5_sync_instance.user_email != user_email:
        _mt5_sync_instance = MT5DashboardSync(dashboard_url, user_email)

    return _mt5_sync_instance
```

Checkpoint — what works now. The desktop side now talks to the dashboard. Run `push_data.py` with test data and check the rows arrive in the database. `mt5_dashboard_sync` will keep that flow running on a schedule.

Chapter 10 — Phase 8 — Desktop GUI

Tkinter ships with Python — no extra install needed. We build a small broker-picker window first to learn the patterns (a window, a frame, a button, a callback), then the full trader-companion app that ties everything in phases 3–7 together under a single tabbed interface.

Files we build in this phase, in order:

- trader_companion/broker_selection.py
- trader_companion/trader_app.py

Python concepts you'll meet in this phase

- Dunder methods (2) · Classes and objects (2) · Decorators (2) · Comprehensions (2) · @classmethod and @staticmethod (2) · Type hints (2) · f-strings (1) · Exceptions (1)

Each is explained in Chapter 2 (the primer). The number in parentheses is how many of this phase's files use that concept.

Step 10.1 — Build trader_companion/broker_selection.py

What to do. Create the file trader_companion/broker_selection.py in your project root and paste in the code shown in this step. The file is **210** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from requirements.txt.

What this file is for. Model + helpers for choosing which broker terminal to connect to when multiple MT5 installations are present.

trader_companion/broker_selection.py

210 loc · 5 classes · 0 functions · 6 imports

Model + helpers for choosing which broker terminal to connect to when multiple MT5 installations are present. It defines **5** classes, across **210** lines. Module docstring: ■ *Broker Selection System - Tradovate Only*

Module docstring

■ Broker Selection System - Tradovate Only Trade Account Connector - Simplified for Tradovate integration

Python concepts demonstrated in this module

• Classes and objects • @classmethod and @staticmethod • Comprehensions • Decorators • Dunder methods • Type hints

Imports — what each one is for

```
import tkinter as tk
```

Why imported. The standard-library GUI toolkit. Powers the desktop trader companion's window.

Used in this file. tk.Toplevel

Example. root = tk.Tk(); tk.Button(root, text='Go').pack()

Other common scenarios.

- ttk.* for the modern themed widgets (Treeview, Notebook, ...)
- after(ms, fn) schedules a callback on the GUI thread
- StringVar / IntVar bind variables to widgets

```
from tkinter import ttk
from tkinter import messagebox
from tkinter import StringVar
from tkinter import BooleanVar
```

Why imported. The standard-library GUI toolkit. Powers the desktop trader companion's window.

Used in this file. StringVar, ttk

Example. root = tk.Tk(); tk.Button(root, text='Go').pack()

Other common scenarios.

- ttk.* for the modern themed widgets (Treeview, Notebook, ...)
- after(ms, fn) schedules a callback on the GUI thread
- StringVar / IntVar bind variables to widgets

```
import logging
```

Why imported. Structured, levelled logging. Replaces print() with filterable, formattable output that can route to files, stderr, syslog, or HTTP endpoints.

Used in this file. logging.getLogger

Example. logging.getLogger(__name__).info('connected to %s', host)

Other common scenarios.

- .debug() / .info() / .warning() / .error() / .exception()
- logger.exception() captures the current traceback automatically
- logging.basicConfig(level=logging.INFO) for quick setup
- Handlers and Formatters route logs to files / streams / syslog

```
from typing import Dict
```

```
from typing import Callable
from typing import Optional
```

Why imported. Type-hint primitives — generics, unions, Optional, Callable, Protocol, TypeVar, TypedDict.

Used in this file. Callable, Dict, Optional

Example. `def lookup(k: str) -> Optional[int]: ...`

Other common scenarios.

- `List[int]` / `Dict[str, Any]` / `Tuple[int, str]` (or bare `list[int]`+ on 3.9+)
- `Callable[[int, int], int]` for function signatures
- Protocol for structural typing (duck typing with checks)
- `TypeVar('T')` for generic functions and classes

```
import os
```

Why imported. Operating-system interface. Path manipulation, environment variables, working-directory operations, exit codes, and thin wrappers around POSIX/Windows syscalls.

Used in this file. *No direct attribute access detected — likely imported for side effects, re-export, or string references.*

Example. `os.path.join(root, 'subdir', 'file.txt')` # joins with the OS-correct separator

Other common scenarios.

- `os.environ.get('API_KEY')` to read environment variables
- `os.makedirs(path, exist_ok=True)` to create nested directories
- `os.listdir(path)` to list a directory's contents
- `os.remove(path)` / `os.rename(src, dst)` to delete or move a file
- `os.getcwd()` / `os.chdir(path)` to inspect or change the working dir

```
from datetime import datetime
```

Why imported. Dates, times, durations. The fundamental temporal types: date, time, datetime, timedelta, timezone.

Used in this file. *No direct attribute access detected — likely imported for side effects, re-export, or string references.*

Example. `datetime.now() - timedelta(days=7)` # one week ago

Other common scenarios.

- `datetime.strptime(s, '%Y-%m-%d')` parses a string
- `datetime.strftime(fmt)` formats one
- `datetime.fromtimestamp(n)` converts a Unix epoch
- `datetime.utcnow()` for UTC (better: `datetime.now(timezone.utc)`)

Classes

```
class BrokerConfig
```

Configuration management for Tradovate broker

```
BROKERS = {'tradovate': {'name': 'Tradovate', 'display_name': 'Tradovate (Web-based)', 'type': 'web', 'co
```

Code (copy-paste safe)

```
class BrokerConfig:
    """
    Configuration management for Tradovate broker
    """

    BROKERS = {
        'tradovate': {
            'name': 'Tradovate',
            'display_name': 'Tradovate (Web-based)',
            'type': 'web',
            'connection_class': 'TradovateAccount',
            'description': 'Web-based futures trading platform',
            'features': [
                '■ Web-based platform (no installation)',
                '■ No additional software required',
                '■ $0.85 per contract commission',
                '■ Free platform and data feeds',
                '■ Easy setup and familiar interface',
                '■ Current stable integration'
            ],
            'requirements': [
                'Tradovate account credentials',
                'Internet connection',
                'Chrome browser'
            ],
            'costs': {
                'platform': 'FREE',
                'data': 'FREE',
                'commission': '$0.85/contract',
                'monthly': '$0'
            },
            'setup_complexity': 'Easy',
            'recommended_for': 'All traders',
            'credentials': ['username', 'password']
        }
    }

    @classmethod
    def get_broker_config(cls, broker_type: str) -> Dict:
        """Get configuration for specific broker"""
        return cls.BROKERS.get(broker_type, {})

    @classmethod
    def list_brokers(cls) -> Dict[str, str]:
        """List all available brokers"""
        return {k: v['display_name'] for k, v in cls.BROKERS.items()}
```

Method: BrokerConfig.get_broker_config

```
@classmethod
def get_broker_config(cls, broker_type: str) -> Dict
```

Get configuration for specific broker

Why these Python concepts were used

- **@classmethod** — Marked **@classmethod** — receives the class itself as the first argument. The standard pattern for alternate constructors that build an instance from a different input shape (e.g., from a dict, a CSV row, or an MT5 order tuple).
- **type-annotated parameters** — Parameters carry type hints (e.g., `broker_type: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> Dict`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. **return** `cls.BROKERS.get(broker_type, {})`.

Code (copy-paste safe)

```
def get_broker_config(cls, broker_type: str) -> Dict:
    """Get configuration for specific broker"""
    return cls.BROKERS.get(broker_type, {})
```

Method: BrokerConfig.list_brokers

```
@classmethod
def list_brokers(cls) -> Dict[str, str]
```

List all available brokers

Why these Python concepts were used

- **@classmethod** — Marked **@classmethod** — receives the class itself as the first argument. The standard pattern for alternate constructors that build an instance from a different input shape (e.g., from a dict, a CSV row, or an MT5 order tuple).
- **return type annotation** — Annotated return type `-> Dict[str, str]`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **dict comprehension** — Builds a dict in one expression `{k: v for k, v in items}` — same intent as a list comprehension but for mappings.

Step by step (top-level body)

1. **return** `{k: v['display_name'] for k, v in cls.BROKERS.items()}`.

Code (copy-paste safe)

```
def list_brokers(cls) -> Dict[str, str]:
    """List all available brokers"""
    return {k: v['display_name'] for k, v in cls.BROKERS.items()}
```

```
class BrokerSelectionSection
```

Simplified broker selection - Tradovate only

Code (copy-paste safe)

```
class BrokerSelectionSection:
```

```

"""
Simplified broker selection - Tradovate only
"""

def __init__(self, parent, on_selection_change: Optional[Callable] = None):
    self.parent = parent
    self.on_selection_change = on_selection_change
    self.confirmed_broker = 'tradovate' # Default to Tradovate

    # Create section frame
    self.section_frame = ttk.LabelFrame(parent, text="Broker Platform", padding=(10, 10))

    # Simple label since only Tradovate is supported
    self.broker_label = ttk.Label(
        self.section_frame,
        text="Using Tradovate (Web-based futures trading)",
        font=("Segoe UI", 10)
    )
    self.broker_label.pack(anchor="w", pady=(0, 5))

    # Features display
    features_text = "■ No installation required • ■ $0.85/contract • ■ Free platform & data"
    self.features_label = ttk.Label(
        self.section_frame,
        text=features_text,
        font=("Segoe UI", 8),
        foreground="#666666"
    )
    self.features_label.pack(anchor="w")

def pack(self, **kwargs):
    """Pack the section frame"""
    self.section_frame.pack(**kwargs)

def get_selected_broker(self) -> str:
    """Get selected broker"""
    return 'tradovate'

```

Method: BrokerSelectionSection.__init__

```
def __init__(self, parent, on_selection_change: Optional[Callable]=None)
```

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `on_selection_change: Optional[Callable]`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **__init__** — The constructor. Runs after Python has allocated the instance; assigns starting attribute values to self.

Step by step (top-level body)

1. Assigns `self.parent = parent`.
2. Assigns `self.on_selection_change = on_selection_change`.
3. Assigns `self.confirmed_broker = 'tradovate'`.

4. Assigns `self.section_frame = ttk.LabelFrame(parent, text='Broker Platform', padding=(1....`
5. Assigns `self.broker_label = ttk.Label(self.section_frame, text='Using Tradovate (Web-....`
6. Calls `self.broker_label.pack(...)` for its side effect.
7. Assigns `features_text = '■ No installation required • ■ $0.85/contract • ■ Free p....`
8. Assigns `self.features_label = ttk.Label(self.section_frame, text=features_text, font=('...`
9. Calls `self.features_label.pack(...)` for its side effect.

Code (copy-paste safe)

```
def __init__(self, parent, on_selection_change: Optional[Callable] = None):
    self.parent = parent
    self.on_selection_change = on_selection_change
    self.confirmed_broker = 'tradovate' # Default to Tradovate

    # Create section frame
    self.section_frame = ttk.LabelFrame(parent, text="Broker Platform", padding=(10, 10))

    # Simple label since only Tradovate is supported
    self.broker_label = ttk.Label(
        self.section_frame,
        text="Using Tradovate (Web-based futures trading)",
        font=("Segoe UI", 10)
    )
    self.broker_label.pack(anchor="w", pady=(0, 5))

    # Features display
    features_text = "■ No installation required • ■ $0.85/contract • ■ Free platform & data"
    self.features_label = ttk.Label(
        self.section_frame,
        text=features_text,
        font=("Segoe UI", 8),
        foreground="#666666"
    )
    self.features_label.pack(anchor="w")
```

Method: BrokerSelectionSection.pack

```
def pack(self, **kwargs)
```

Pack the section frame

Why these Python concepts were used

- ****kwargs** — Accepts arbitrary keyword arguments. Usually for forwarding to another function (a thin wrapper) or to support optional named parameters without listing them all in the signature.

Step by step (top-level body)

1. Calls `self.section_frame.pack(...)` for its side effect.

Code (copy-paste safe)

```
def pack(self, **kwargs):
    """Pack the section frame"""
    self.section_frame.pack(**kwargs)
```

Method: BrokerSelectionSection.get_selected_broker

```
def get_selected_broker(self) -> str

Get selected broker
```

Why these Python concepts were used

- **return type annotation** — Annotated return type -> str. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. **return** 'tradovate'.

Code (copy-paste safe)

```
def get_selected_broker(self) -> str:
    """Get selected broker"""
    return 'tradovate'
```

```
class BrokerCredentialsDialog
```

Credentials dialog - simplified for Tradovate only

Code (copy-paste safe)

```
class BrokerCredentialsDialog:
    """
    Credentials dialog - simplified for Tradovate only
    """

    def __init__(self, parent, broker_id: str = "tradovate"):
        self.parent = parent
        self.broker_id = broker_id
        self.result = None
        self.credentials = {}

    def show(self):
        """Show credentials dialog - for Tradovate, return empty (credentials handled by combine cards)"""
        # For Tradovate, credentials are handled in the combine cards
        return "ok", {}
```

Method: BrokerCredentialsDialog.__init__

```
def __init__(self, parent, broker_id: str='tradovate')
```

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., broker_id: str). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **__init__** — The constructor. Runs after Python has allocated the instance; assigns starting attribute values to self.

Step by step (top-level body)

1. Assigns self.parent = parent.

2. Assigns `self.broker_id = broker_id`.
3. Assigns `self.result = None`.
4. Assigns `self.credentials = {}`.

Code (copy-paste safe)

```
def __init__(self, parent, broker_id: str = "tradovate"):
    self.parent = parent

    """Cancel selection"""

```

```
self.root.destroy()
```

Method: BrokerSelectionView.__init__

```
def __init__(self, master, on_confirm: Optional[Callable]=None)
```

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `on_confirm: Optional[Callable]`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **__init__** — The constructor. Runs after Python has allocated the instance; assigns starting attribute values to self.

Step by step (top-level body)

1. Assigns `self.master = master`.
2. Assigns `self.on_confirm = on_confirm`.
3. Assigns `self.selected_broker = StringVar(value='tradovate')`.
4. Assigns `self.root = tk.Toplevel(master)`.
5. Calls `self.root.title(...)` for its side effect.
6. Calls `self.root.geometry(...)` for its side effect.
7. Calls `self.root.resizable(...)` for its side effect.
8. Calls `self.root.transient(...)` for its side effect.
9. Calls `self.root.grab_set(...)` for its side effect.
10. Calls `self._create_widgets(...)` for its side effect.

Code (copy-paste safe)

```
def __init__(self, master, on_confirm: Optional[Callable] = None):
    self.master = master
    self.on_confirm = on_confirm
    self.selected_broker = StringVar(value="tradovate")

    # Create main window
    self.root = tk.Toplevel(master)
    self.root.title("Broker Selection")
    self.root.geometry("500x300")
    self.root.resizable(False, False)

    # Center window
    self.root.transient(master)
    self.root.grab_set()

    self._create_widgets()
```

Method: BrokerSelectionView._create_widgets

```
def _create_widgets(self)
```

Create dialog widgets

Step by step (top-level body)

1. Assigns `header_frame = ttk.Frame(self.root, padding=(20, 20, 20, 10))`.
2. Calls `header_frame.pack(...)` for its side effect.
3. Assigns `header_label = ttk.Label(header_frame, text='Trading Platform Selection'....`
4. Calls `header_label.pack(...)` for its side effect.
5. Assigns `content_frame = ttk.Frame(self.root, padding=(20, 0, 20, 20))`.
6. Calls `content_frame.pack(...)` for its side effect.
7. Assigns `info_text = '■ Tradovate Platform\n\n■ Web-based futures trading plat....`
8. Assigns `info_label = ttk.Label(content_frame, text=info_text, font=('Segoe UI'....`
9. Calls `info_label.pack(...)` for its side effect.
10. Assigns `button_frame = ttk.Frame(content_frame)`.
11. Calls `button_frame.pack(...)` for its side effect.
12. Calls `tk.Button(button_frame, text='Continue with Tradovate',
command=self._confirm_selection).pack(...)` for its side effect.
13. Calls `tk.Button(button_frame, text='Cancel', command=self._cancel).pack(...)` for its side effect.

Code (copy-paste safe)

```
def _create_widgets(self):
    """Create dialog widgets"""
    # Header
    header_frame = ttk.Frame(self.root, padding=(20, 20, 20, 10))
    header_frame.pack(fill="x")

    header_label = ttk.Label(
        header_frame,
        text="Trading Platform Selection",
        font=("Segoe UI", 14, "bold")
    )
    header_label.pack()

    # Content
    content_frame = ttk.Frame(self.root, padding=(20, 0, 20, 20))
    content_frame.pack(fill="both", expand=True)

    # Tradovate info
    info_text = """■ Tradovate Platform

■ Web-based futures trading platform

Enter your Tradovate credentials in the combine sections to begin trading."""

    info_label = ttk.Label(
        content_frame,
        text=info_text,
```

```

        font=("Segoe UI", 10),
        justify="left"
    )
    info_label.pack(pady=(0, 20))

    # Buttons
    button_frame = ttk.Frame(content_frame)
    button_frame.pack(fill="x")

    ttk.Button(
        button_frame,
        text="Continue with Tradovate",
        command=self._confirm_selection
    ).pack(side="right", padx=(10, 0))

    ttk.Button(
        button_frame,
        text="Cancel",
        command=self._cancel
    ).pack(side="right")

```

Method: BrokerSelectionView._confirm_selection

```
def _confirm_selection(self)
```

Confirm broker selection

Step by step (top-level body)

1. if self.on_confirm: branches conditionally.
2. Calls self.root.destroy(...) for its side effect.

Code (copy-paste safe)

```

def _confirm_selection(self):
    """Confirm broker selection"""
    if self.on_confirm:
        self.on_confirm("tradovate")
    self.root.destroy()

```

Method: BrokerSelectionView._cancel

```
def _cancel(self)
```

Cancel selection

Step by step (top-level body)

1. Calls self.root.destroy(...) for its side effect.

Code (copy-paste safe)

```

def _cancel(self):
    """Cancel selection"""
    self.root.destroy()

```

```
class BrokerCredentialsDialog
```

Code (copy-paste safe)

```
class BrokerCredentialsDialog:
    def __init__(self, parent, broker_id="tradovate"):
        pass

    def show(self):
        return "ok", {}
```

Method: BrokerCredentialsDialog.__init__

```
def __init__(self, parent, broker_id='tradovate')
```

Why these Python concepts were used

- **__init__** — The constructor. Runs after Python has allocated the instance; assigns starting attribute values to self.

Step by step (top-level body)

1. **pass** (placeholder).

Code (copy-paste safe)

```
def __init__(self, parent, broker_id="tradovate"):
    pass
```

Method: BrokerCredentialsDialog.show

```
def show(self)
```

Step by step (top-level body)

1. **return** ('ok', {}).

Code (copy-paste safe)

```
def show(self):
    return "ok", {}
```

Step 10.2 — Build trader_companion/trader_app.py

What to do. Create the file trader_companion/trader_app.py in your project root and paste in the code shown in this step. The file is **8659** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from requirements.txt.

What this file is for. The Tkinter main window. Wires together the MT5 connection, the prop-firm scrapers, the trade-limit manager, and the hedge protector under a tabbed UI. The largest single file in the codebase.

trader_companion/trader_app.py

8659 loc · 2 classes · 3 functions · 15 imports

The Tkinter main window. Wires together the MT5 connection, the prop-firm scrapers, the trade-limit manager, and the hedge protector under a tabbed UI. The largest single file in the codebase. It defines **2** classes and **3** module-level functions, across **8,659** lines.

Python concepts demonstrated in this module

• Classes and objects • @classmethod and @staticmethod • Comprehensions • Context managers (with-statements) • Decorators • Dunder methods • Exceptions • f-strings • Lambdas • Type hints • Walrus operator (:=)

Imports — what each one is for

```
import sys
```

Why imported. Access to the running interpreter — argv, stdin/stdout, exit codes, the import search path, and the platform name.

Used in this file. sys._MEIPASS, sys.path, sys.path.insert

Example. sys.exit(1) # terminate the process with a non-zero status

Other common scenarios.

- sys.argv[1:] reads the command-line arguments
- sys.path.insert(0, 'extra') prepends to the import search path
- sys.stderr.write(msg) writes to standard error
- sys.platform tells you 'win32', 'linux', or 'darwin'
- sys.modules is the global cache of already-imported modules

```
import os
```

Why imported. Operating-system interface. Path manipulation, environment variables, working-directory operations, exit codes, and thin wrappers around POSIX/Windows syscalls.

Used in this file. os.add_dll_directory, os.environ, os.environ.get, os.path, os.path.abspath, os.path.basename, os.path.dirname, os.path.exists

Example. os.path.join(root, 'subdir', 'file.txt') # joins with the OS-correct separator

Other common scenarios.

- os.environ.get('API_KEY') to read environment variables
- os.makedirs(path, exist_ok=True) to create nested directories
- os.listdir(path) to list a directory's contents
- os.remove(path) / os.rename(src, dst) to delete or move a file
- os.getcwd() / os.chdir(path) to inspect or change the working dir

```
import sys
```

Why imported. Access to the running interpreter — argv, stdin/stdout, exit codes, the import search path, and the platform name.

Used in this file. sys._MEIPASS, sys.path, sys.path.insert

Example. sys.exit(1) # terminate the process with a non-zero status

Other common scenarios.

- sys.argv[1:] reads the command-line arguments
- sys.path.insert(0, 'extra') prepends to the import search path
- sys.stderr.write(msg) writes to standard error
- sys.platform tells you 'win32', 'linux', or 'darwin'
- sys.modules is the global cache of already-imported modules

```
import os
```

Why imported. Operating-system interface. Path manipulation, environment variables, working-directory operations, exit codes, and thin wrappers around POSIX/Windows syscalls.

Used in this file. os.add_dll_directory, os.environ, os.environ.get, os.path, os.path.abspath, os.path.basename, os.path.dirname, os.path.exists

Example. os.path.join(root, 'subdir', 'file.txt') # joins with the OS-correct separator

Other common scenarios.

- os.environ.get('API_KEY') to read environment variables
- os.makedirs(path, exist_ok=True) to create nested directories
- os.listdir(path) to list a directory's contents
- os.remove(path) / os.rename(src, dst) to delete or move a file
- os.getcwd() / os.chdir(path) to inspect or change the working dir

```
import json
```

Why imported. JSON encoding and decoding — the standard wire format for config files, API payloads, and inter-process messages.

Used in this file. json.dump, json.dumps, json.load

Example. json.loads(response.text) # parse a JSON string to dict

Other common scenarios.

- json.dumps(obj, indent=2) for pretty-printing
- json.dump(obj, file) / json.load(file) for file I/O
- default=str handles non-serialisable types like datetime
- object_hook= customises decoding (e.g., to dataclass instances)

```
import gzip as _gzip
```

Why imported. Read/write gzip-compressed streams.

Used in this file. _gzip.compress

Example. with gzip.open('logs.gz', 'rt') as f: ...

Other common scenarios.

- gzip.compress(b) / gzip.decompress(b) for in-memory blobs
- Pair with shutil.copyfileobj for streaming compression

```
import requests
```

Why imported. The de-facto Python HTTP client. Synchronous; trades raw speed for an extremely friendly API.

Used in this file. requests.exceptions, requests.exceptions.ConnectionError, requests.exceptions.Timeout, requests.get, requests.post

Example. requests.get(url, timeout=10).json()

Other common scenarios.

- Session() reuses TCP connections across calls
- params=, headers=, json=, data= for query/body shapes
- raise_for_status() turns 4xx/5xx into an exception
- stream=True for large downloads

```
import time
```

Why imported. Timestamps and sleep. Lower-level than datetime — works in Unix-epoch seconds.

Used in this file. time.sleep, time.time

Example. time.sleep(1.5) # pause this thread for 1.5 seconds

Other common scenarios.

- time.time() returns seconds since the epoch
- time.monotonic() for measuring elapsed time (never goes backward)
- time.perf_counter() for high-precision benchmarking
- time.strftime / time.strptime mirror the datetime versions

```
from datetime import datetime
```

Why imported. Dates, times, durations. The fundamental temporal types: date, time, datetime, timedelta, timezone.

Used in this file. datetime

Example. datetime.now() - timedelta(days=7) # one week ago

Other common scenarios.

- datetime.strptime(s, '%Y-%m-%d') parses a string
- datetime.strftime(fmt) formats one
- datetime.fromtimestamp(n) converts a Unix epoch
- datetime.utcnow() for UTC (better: datetime.now(timezone.utc))

```
import threading
```

Why imported. Threads and synchronisation primitives. Used when work is I/O-bound and the GIL is not a bottleneck (the GIL prevents speed-up on CPU-bound work).

Used in this file. `threading.Event`, `threading.Lock`, `threading.Thread`

Example. `Thread(target=worker, args=(q,), daemon=True).start()`

Other common scenarios.

- `Lock` / `RLock` to guard shared state
- `Event` for one-shot signals between threads
- `Queue` (from `queue`) for producer/consumer patterns
- `threading.local()` for thread-local storage

```
from concurrent.futures import ThreadPoolExecutor
from concurrent.futures import as_completed
```

Why imported. `concurrent.futures` — high-level pools of threads or processes. Submit work, get back a `Future` you can await.

Used in this file. `ThreadPoolExecutor`, `as_completed`

Example. `with ThreadPoolExecutor(8) as ex: results = list(ex.map(fetch, urls))`

Other common scenarios.

- `ProcessPoolExecutor` for CPU-bound work (sidesteps the GIL)
- `ex.submit(fn, *args)` returns a `Future`
- `as_completed(futures)` yields them in completion order

```
from collections import defaultdict
```

Why imported. Specialised container datatypes that the `dict` / `list` / `tuple` / `set` primitives don't cover.

Used in this file. `defaultdict`

Example. `Counter(words)` # multiset that counts occurrences

Other common scenarios.

- `defaultdict(list)` auto-creates a default value on missing keys
- `deque(maxlen=N)` is a double-ended bounded queue
- `OrderedDict` (mostly redundant since 3.7 — dicts preserve order)
- `namedtuple('Point', 'x y')` for tiny immutable record types

```
from typing import Dict
```

Why imported. Type-hint primitives — generics, unions, `Optional`, `Callable`, `Protocol`, `TypeVar`, `TypedDict`.

Used in this file. `Dict`

Example. `def lookup(k: str) -> Optional[int]: ...`

Other common scenarios.

- `List[int]` / `Dict[str, Any]` / `Tuple[int, str]` (or bare `list[int]`+ on 3.9+)
- `Callable[[int, int], int]` for function signatures
- Protocol for structural typing (duck typing with checks)
- `TypeVar('T')` for generic functions and classes

`import re`

Why imported. Regular expressions. Pattern matching, search, replace, and text extraction.

Used in this file. `re.IGNORECASE`, `re.findall`, `re.match`, `re.search`, `re.split`

Example. `re.search(r'\d{3}-\d{4}', text)` # returns a `Match` or `None`

Other common scenarios.

- `re.findall(pattern, text)` for every non-overlapping match
- `re.sub(pattern, repl, text)` to replace occurrences
- `re.compile(...)` to reuse a pattern (faster in a loop)
- Named groups: `r'(?P<year>\d{4})'` lets you do `m.group('year')`

`import random`

Why imported. Pseudo-random numbers — fine for jitter, sampling, shuffling. NEVER for security; use secrets for that.

Used in this file. `random.choice`, `random.randint`, `random.sample`

Example. `random.uniform(0.5, 1.5)` # backoff jitter

Other common scenarios.

- `random.choice(seq)` picks one item
- `random.shuffle(list)` rearranges in place
- `random.seed(n)` makes the sequence reproducible
- `random.sample(seq, k)` draws `k` unique items

Module constants

Each line below is followed by a plain-English note explaining what it does and why it is written that way.

`APP_VERSION = '1.5.6'`

String literal — fixed at code-load time.

`RELEASE_DISABLE_HEDGE_GUARD = True`

Module-level constant — bound once at import time and referenced from the functions and classes below.

`RELEASE_DISABLE_STATUS_POLL = True`

Module-level constant — bound once at import time and referenced from the functions and classes below.

`RELEASE_DISABLE_AUTO_STATUS_UPDATES = True`

Module-level constant — bound once at import time and referenced from the functions and classes below.

```
RELEASE_DISABLE_PROP_DASHBOARD_ACCESS = True
```

Module-level constant — bound once at import time and referenced from the functions and classes below.

```
RELEASE_DISABLE_PUSH_BILLING = True
```

Module-level constant — bound once at import time and referenced from the functions and classes below.

```
_TRADOVATE_IMPORT_ERROR = str(_trado_err) if not TRADOVATE_AVAILABLE and '_trado_err' in dir(  
    ) and _trado_err else None
```

Module-level constant — bound once at import time and referenced from the functions and classes below.

```
_TOPSTEPX_IMPORT_ERROR = str(_tsx_err) if not TOPSTEPX_AVAILABLE and '_tsx_err' in dir(  
    ) and _tsx_err else None
```

Module-level constant — bound once at import time and referenced from the functions and classes below.

```
_FUNDEDNEXT_IMPORT_ERROR = str(_fn_err) if not FUNDEDNEXT_AVAILABLE and '_fn_err' in dir(  
    ) and _fn_err else None
```

Module-level constant — bound once at import time and referenced from the functions and classes below.

```

Method: MT5DataPusher.__init__

```
def __init__(self, dashboard_url='http://127.0.0.1:5001', api_key=None)
```

Why these Python concepts were used

- **__init__** — The constructor. Runs after Python has allocated the instance; assigns starting attribute values to self.

Step by step (top-level body)

1. Assigns `self.dashboard_url = dashboard_url.rstrip('/')`.
2. Assigns `self.api_key = api_key`.
3. Assigns `self.connected = False`.
4. Assigns `self.login = None`.
5. Assigns `self.server = None`.

Code (copy-paste safe)

```
def __init__(self, dashboard_url="http://127.0.0.1:5001", api_key=None):
    self.dashboard_url = dashboard_url.rstrip('/')
    self.api_key = api_key
    self.connected = False
    self.login = None
    self.server = None
```

Method: MT5DataPusher.connect_mt5

```
def connect_mt5(self, login=None, password=None, server=None, terminal_path=None)
```

Connect to MT5 terminal.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **if not MT5_AVAILABLE**: branches conditionally.
2. Assigns `init_params = {}`.
3. **if terminal_path**: branches conditionally.
4. **if not mt5.initialize(**init_params)**: branches conditionally.
5. **if login and password and server**: branches conditionally.
6. Assigns `self.connected = True`.
7. Assigns `account = mt5.account_info()`.
8. **if account**: branches conditionally.

9. **return** (True, 'Connected to MT5 (no account logged in)').

Code (copy-paste safe)

```
def connect_mt5(self, login=None, password=None, server=None, terminal_path=None):

Push all data to the dashboard.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **set comprehension** — Builds a set in one expression — usually to deduplicate the result of a transform.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

Method: MT5DataPusher._process_deals_with_new_parser

```
def _process_deals_with_new_parser(self, deals, evaluations)
```

Process deals using the new MT5 comment parser. Matches account numbers and updates the correct hedge result fields.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

    return None
```

Method: MT5DataPusher._calculate_farming_day

```
def _calculate_farming_day(self, farming_date_str, evaluations, eval_idx)
```

Calculate which farming day number to use based on the date. Farming dates in comments are DDMMYY format (e.g., 210126 = Jan 21, 2026). We need to figure out which day number (1-34) this corresponds to. Strategy: Look at existing farming dates in the evaluation to determine sequence, or use the first farming date as day 1 and count from there.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Lazy import from datetime.
2. `if isinstance(farming_date_str, str):` branches conditionally (with an **else/elif** arm).
3. `if not farming_date:` branches conditionally.
4. Assigns `ev = evaluations[eval_idx]` if `eval_idx < len(evaluations)` else `{}`.
5. `for day_num in range(1, 51):` iterates.
6. `return 50`.

Code (copy-paste safe)

```
def _calculate_farming_day(self, farming_date_str, evaluations, eval_idx):
    """
    Calculate which farming day number to use based on the date.

    Farming dates in comments are DDMMYY format (e.g., 210126 = Jan 21, 2026).
    We need to figure out which day number (1-34) this corresponds to.

    Strategy: Look at existing farming dates in the evaluation to determine sequence,
    or use the first farming date as day 1 and count from there.
    """
    from datetime import datetime

    # Parse the farming date
    if isinstance(farming_date_str, str):
        try:
            farming_date = datetime.fromisoformat(farming_date_str)
        except:
            return None
    else:
        farming_date = farming_date_str

    if not farming_date:
        return None

    # Get the evaluation record to check for existing farming dates
```

```

ev = evaluations[eval_idx] if eval_idx < len(evaluations) else {}

# Find the first empty farming day slot
for day_num in range(1, 51):
    field_name = f"Hedge Day {day_num}"
    existing_value = ev.get(field_name)

    # Check if this slot is empty or has no value
    if existing_value is None or existing_value == '' or existing_value == 0:
        return day_num

# All slots full, return the last one
return 50

```

Method: MT5DataPusher._process_deals_legacy

```
def _process_deals_legacy(self, deals, evaluations)
```

Legacy deal processing for backward compatibility.

Why these Python concepts were used

- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **lambda** — Uses a single-expression anonymous function — typically as the `key=` for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.
- **__init__** — The constructor. Runs after Python has allocated the instance; assigns starting attribute values to `self`.

Step by step (top-level body)

1. **if** `CTK_AVAILABLE`: branches conditionally (with an **else/elif** arm).
2. Calls `self.root.title(...)` for its side effect.
3. Calls `self.root.geometry(...)` for its side effect.
4. Calls `self.root.minsize(...)` for its side effect.
5. **if** `CTK_AVAILABLE`: branches conditionally (with an **else/elif** arm).
6. Calls `self.root.resizable(...)` for its side effect.
7. Calls `self.root.bind(...)` for its side effect.
8. Assigns `self._section_logo = None`.
9. **try** block with 1 **except** clause.
10. Assigns `self.pusher = MT5DataPusher()`.
11. Assigns `self.auto_push_enabled = False`.
12. Assigns `self.auto_push_thread = None`.
13. Assigns `self._push_lock = threading.Lock()`.
14. Assigns `self._push_in_progress = False`.
15. ... and 23 more statement(s) in the body.

Code (copy-paste safe)

```
def __init__(self):
    # ■■ CTK root window ■■
    if CTK_AVAILABLE:
        ctk.set_appearance_mode("Dark")

Show a full-screen login/email verification screen — always required.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns saved_email = "".
2. Assigns config_path = os.path.join(os.path.dirname(__file__), 'trader_config.js....
3. **if** os.path.exists(config_path): branches conditionally.

def _verify_login(self)
```

Verify the email against the dashboard API.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.

Step by step (top-level body)

1. Assigns email = self._login_email.get().strip().
2. if not email: branches conditionally.
3. Calls self._login_btn.configure(...) for its side effect.
4. Calls self._login_status.configure(...) for its side effect.
5. Calls self.root.update_idletasks(...) for its side effect.
6. Defines a nested function _check(...).
7. Calls threading.Thread(target=_check, daemon=True).start(...) for its side effect.

Code (copy-paste safe)

```
def _verify_login(self):
    """Verify the email against the dashboard API."""
    email = self._login_email.get().strip()
    if not email:
        self._login_status.configure(text="Please enter an email address.")
        return

    self._login_btn.configure(state="disabled", text="VERIFYING...")
    self._login_status.configure(text="", text_color=self.C_TEXT_DIM)
    self.root.update_idletasks()

    def _check():
        try:
            response = requests.post(
                "https://www.tradeopss.com/api/client/auth",
                json={"email": email},
                headers={"Content-Type": "application/json"},
                timeout=30
            )
            if response.status_code == 200:
                data = response.json()
                if data.get("status") == "success":
                    self.root.after(0, lambda: self._finish_login(email))
                    return
                else:

    self.client_email_entry.insert(0, email)
    self.root.after(200, self.lookup_client)

```

Method: TradeOpssAIApp._section_card

```
def _section_card(self, parent, title='', icon='', **kw)
```

Create a styled card frame with optional title strip.

Why these Python concepts were used

- ****kw** — Accepts arbitrary keyword arguments. Usually for forwarding to another function (a thin wrapper) or to support optional named parameters without listing them all in the signature.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns card = ctk.CTkFrame(parent, fg_color=self.C_BG_SEC, corner_radiu....
2. if title and CTK_AVAILABLE: branches conditionally.
3. return card.

Code (copy-paste safe)

```

self.auto_push_thread = None
```

Method: TradeOpssAIApp._tick_live_clock

```
def _tick_live_clock(self)
```

Update the live display clock every second.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def _tick_live_clock(self):
    """Update the live display clock every second."""
    try:
        self._live_clock_var.set(datetime.now().strftime("%H:%M:%S"))
        self.root.after(1000, self._tick_live_clock)
    except Exception:
        pass
```

Method: TradeOpssAIApp._add_activity

```
def _add_activity(self, text, kind='info')
```

Add an entry to the Live Activity display panel. kind: 'info', 'trade', 'push', 'error', 'queue', 'success'

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `COLORS = {'info': '#64748B', 'trade': '#F59E0B', 'push': '#3B82F6'....`
2. Assigns `ICONS = {'info': '■', 'trade': '■', 'push': '■', 'error': '✕', 'q....`
3. **if not CTK_AVAILABLE**: branches conditionally.
4. Assigns `color = COLORS.get(kind, COLORS['info'])`.
5. Assigns `icon = ICONS.get(kind, '•')`.

    self._build_trading_engine_ui(parent)

```

Method: TradeOpssAIApp._build_dashboard_tab

```
def _build_dashboard_tab(self, parent)
```

Build the Dashboard section — compact layout.

Why these Python concepts were used

- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns settings = parent.
2. Assigns conn_card = self._section_card(settings, 'CONNECTION TARGET', '■').
3. Calls conn_card.pack(...) for its side effect.
4. Assigns conn_inner = ctk.CTkFrame(conn_card, fg_color='transparent') if CTK_AV....
5. Calls conn_inner.pack(...) for its side effect.
6. **if** CTK_AVAILABLE: branches conditionally.
7. Assigns self.target_var = tk.StringVar().
8. Assigns self.url_keys = ['TradeOps (Production)', 'Localhost (Development)'].
9. Assigns self.url_values = {'TradeOps (Production)': 'https://www.tradeopss.com', '....
10. **if** CTK_AVAILABLE: branches conditionally (with an **else/elif** arm).
11. Assigns self.url_entry = ttk.Entry(settings).
12. Calls self.url_entry.insert(...) for its side effect.
13. Defines a nested function on_target_change(...).
14. **if** CTK_AVAILABLE: branches conditionally (with an **else/elif** arm).
15. ... and 26 more statement(s) in the body.

Code (copy-paste safe)

```

Method: TradeOpssAIApp.log

```
def log(self, message, level='INFO')
```

Add a message to the log and the live activity display.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns timestamp = datetime.now().strftime('%H:%M:%S').
2. Calls self.log_text.insert(...) for its side effect.
3. Calls self.log_text.see(...) for its side effect.
4. Assigns kind = 'info'.
5. Assigns msg_lower = message.lower().
6. if level == 'ERROR' or '■' in message or 'failed' in msg_lower: branches conditionally (with an **else/elif** arm).
7. **try** block with 1 **except** clause.
8. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

def log(self, message, level="INFO"):
    """Add a message to the log and the live activity display."""
    timestamp = datetime.now().strftime("%H:%M:%S")

```

```

self.log_text.insert(tk.END, f"[{timestamp}] {message}\n")
self.log_text.see(tk.END)
# Feed into live display
kind = "info"
msg_lower = message.lower()
if level == "ERROR" or "■" in message or "failed" in msg_lower:
    kind = "error"
elif "■" in message or "success" in msg_lower:
    kind = "success"
elif "trade" in msg_lower or "buy" in msg_lower or "sell" in msg_lower or "■" in message:
    kind = "trade"
elif "push" in msg_lower or "■" in message or "syncd" in msg_lower:
    kind = "push"
elif "queue" in msg_lower or "scheduled" in msg_lower or "■" in message:
    kind = "queue"

threading.Thread(target=_do_lookup, daemon=True).start()

```

Method: TradeOpssAIApp.toggle_mt5_connection

```
def toggle_mt5_connection(self)
```

Connect or disconnect from MT5.

Why these Python concepts were used

- **ternary expression** — Uses `x` if `cond` else `y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **if** `self.pusher.connected`: branches conditionally (with an **else/elif** arm).

Code (copy-paste safe)

```

def toggle_mt5_connection(self):
    """Connect or disconnect from MT5."""
    if self.pusher.connected:
        success, msg = self.pusher.disconnect_mt5()
        self.mt5_btn.configure(text="Connect to MT5")
        self.log(msg)
    else:
        login = self.mt5_login.get().strip()
        password = self.mt5_password.get()
        server = self.mt5_server.get().strip()

        success, msg = self.pusher.connect_mt5(login, password, server)
        if success:
            self.mt5_btn.configure(text="Disconnect MT5")
            self.log(msg, "INFO" if success else "ERROR")

```

Method: TradeOpssAIApp._push_billing_data

```
def _push_billing_data(self)
```

Push only firm billing (actual fees & payouts) to the dashboard.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with `append`, and clearer about intent: this is a transform, not a side-effecting loop.

- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.

Step by step (top-level body)

1. **if** RELEASE_DISABLE_PUSH_BILLING: branches conditionally.
2. **if** not self._firm_billing_summary: branches conditionally.
3. Assigns dashboard_url = self.url_entry.get().strip().rstrip('/').
4. Assigns email = self.client_email_entry.get().strip().
5. **if** not self.client_info: branches conditionally.
6. Defines a nested function _do_push(...).
7. Calls threading.Thread(target=_do_push, daemon=True).start(...) for its side effect.

Code (copy-paste safe)

```

Push data to dashboard - NO API KEY REQUIRED.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.

Step by step (top-level body)

1. Assigns `dashboard_url = self.url_entry.get().strip().rstrip('/')`.
2. Assigns `email = self.client_email_entry.get().strip()`.
3. **if** `not self.client_info`: branches conditionally.
4. Assigns `client_name = self.client_info.get('client', '')`.

5. **if** not `client_name`: branches conditionally.
6. **with** `self._push_lock`: enters a context manager.
7. **if** `hasattr(self, 'push_btn_live')` and `self.push_btn_live`: branches conditionally.
8. Calls `self.log(...)` for its side effect.
9. Calls `self.status_var.set(...)` for its side effect.
10. Defines a nested function `_do_push(...)`.
11. Calls `threading.Thread(target=_do_push, daemon=True).start(...)` for its side effect.

Code (copy-paste safe)

```

Heavy push work — runs on a background thread.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **dict comprehension** — Builds a dict in one expression (`{k: v for k, v in items}`) — same intent as a list comprehension but for mappings.
- **set comprehension** — Builds a set in one expression — usually to deduplicate the result of a transform.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Defines a nested function `_log(...)`.
2. Defines a nested function `_status(...)`.

3. Assigns `account = self.pusher.get_account_info(include_balance_history=False)`.
4. `if not account`: branches conditionally.
5. `if account`: branches conditionally.
6. Assigns `positions = self.pusher.get_positions()`.
7. `if positions is None`: branches conditionally.
8. Assigns `_today_cutoff = time.time() - 86400`.
9. Assigns `raw_deals = self.pusher.get_deals(days=1)` or `[]`.
10. Assigns `_fa_history_days = 365`.
11. Assigns `_login_key = str(account.get('login', 'unknown'))`.
12. `if not hasattr(self, '_fa_history_cache')`: branches conditionally.
13. Assigns `_cached = self._fa_history_cache.get(_login_key)`.
14. Assigns `_now = time.time()`.
15. ... and 40 more statement(s) in the body.

Method: TradeOpssAIApp._push_hedging_review_worker

```
def _push_hedging_review_worker(self, dashboard_url, email, account)
```

Send hedging review payload — refreshes account totals in the background if needed.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.

Step by step (top-level body)

1. Defines a nested function `_log(...)`.
2. Defines a nested function `_status(...)`.
3. `if self.pusher.connected:` branches conditionally.
4. Assigns `deposits = float(account.get('total_deposits', 0) or 0)`.
5. Assigns `withdrawals = float(account.get('total_withdrawals', 0) or 0)`.
6. Assigns `balance = float(account.get('balance', 0) or 0)`.
7. Calls `_log(...)` for its side effect.

8. Assigns payload = {'email': email, 'total_deposits': deposits, 'total_withd....

9. try block with 3 except clauses.

Code (copy-paste safe)

```
def _push_hedging_review_worker(self, dashboard_url, email, account):
    """Send hedging review payload – refreshes account totals in the background if needed."""
    def _log(msg, level="INFO"):

Method: TradeOpssAIApp.sync_hedge_results

```
def sync_hedge_results(self)
```

Sync hedge results from MT5 deal comments to evaluation records. Parses deal comments to extract account number and stage: - Challenge: {account}_CH{n} - Funded: {account}_FU{n} - Farming: {account}_FA{n}_{DD/MM} Then updates the appropriate Hedge Result fields in evaluations.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression ([f(x) for x in xs]). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

```

Method: TradeOpssAIApp.show_aggregated_data

```
def show_aggregated_data(self)
```

Show aggregated deal data by account and phase. Uses the new comment parser to group deals.

Why these Python concepts were used

- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. if not self.pusher.connected: branches conditionally.
2. Calls self.log(...) for its side effect.
3. Calls self.log(...) for its side effect.
4. Calls self.log(...) for its side effect.

5. Assigns `result = self.pusher.get_deals_grouped_by_phase(days=365)`.
6. Assigns `aggregated = result.get('aggregated', [])`.
7. Assigns `unmatched = result.get('unmatched', [])`.
8. Assigns `summary = result.get('summary', {})`.
9. Calls `self.log(...)` for its side effect.
10. Calls `self.log(...)` for its side effect.
11. **if** `not aggregated`: branches conditionally.
12. Assigns `by_account = {}`.
13. **for** `agg` in `aggregated`: iterates.
14. Calls `self.log(...)` for its side effect.
15. ... and 5 more statement(s) in the body.

Method: TradeOpssAIApp.push_by_comment

```
def push_by_comment(self)
```

Push hedge results to dashboard by matching MT5 order comments to evaluation accounts. This uses the TradeAccountConnector comment format: - {TradovateAccountNumber}_CH{1-4}: Challenge Hedge Results 1-5 - {TradovateAccountNumber}_FD{0-4}: Funded Hedge Results - {TradovateAccountNumber}_DD{1-4}: Double Dip (funded hedge results) - {TradovateAccountNumber}_FA or _FA_DDMMYY: Farming Hedge Days The function: 1. Aggregates MT5 deals by account/phase from comments 2. Sends aggregated data to dashboard 3. Dashboard matches account numbers and updates hedge results

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns dashboard_url = self.url_entry.get().strip().rstrip('/').
2. Assigns email = self.client_email_entry.get().strip().
3. **if** not self.client_info: branches conditionally.

4. `if not self.pusher.connected:` branches conditionally.
5. `if not COMMENT_PARSER_AVAILABLE:` branches conditionally.
6. Assigns `client_name = self.client_info.get('client', '')`.
7. Calls `self.log(...)` for its side effect.
8. Calls `self.log(...)` for its side effect.
9. Calls `self.log(...)` for its side effect.
10. Calls `self.log(...)` for its side effect.
11. Calls `self.log(...)` for its side effect.
12. Calls `self.log(...)` for its side effect.
13. Calls `self.log(...)` for its side effect.
14. Calls `self.log(...)` for its side effect.
15. ... and 23 more statement(s) in the body.

Code (copy-paste safe)

```

```

Method: TradeOpssAIApp.import_from_csv

```
def import_from_csv(self)
```

Import evaluation data from a CSV file previously exported from the dashboard.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.

Step by step (top-level body)

1. Assigns email = self.client_email_entry.get().strip().
2. Assigns csv_path = self.csv_path_var.get().strip().

Method: TradeOpssAIApp.migrate_from_sheet

```
def migrate_from_sheet(self)
```

Migrate data from Google Sheets to the dashboard with verification.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.

Step by step (top-level body)

1. Assigns `email = self.client_email_entry.get().strip()`.
2. Assigns `sheet_url = self.sheet_url_entry.get().strip()`.
3. Assigns `dashboard_url = self.url_entry.get().strip().rstrip('/')`.
4. **if not email**: branches conditionally.
5. **if not sheet_url**: branches conditionally.
6. **if 'docs.google.com/spreadsheets' not in sheet_url**: branches conditionally.
7. Calls `self.log(...)` for its side effect.
8. Calls `self.status_var.set(...)` for its side effect.
9. Calls `self.root.update_idletasks(...)` for its side effect.
10. Defines a nested function `_do_migrate(...)`.
11. Calls `threading.Thread(target=_do_migrate, daemon=True).start(...)` for its side effect.

```

Method: TradeOpssAIApp.verify_stats

```
def verify_stats(self, local_stats, dashboard_stats)
```

Compare local stats with dashboard stats and return list of discrepancies.

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.

Step by step (top-level body)

1. Assigns discrepancies = [].
2. Assigns tolerance = 0.01.
3. Defines a nested function compare(...).
4. Assigns local_prof = local_stats.get('profitability_completed', {}).
5. Assigns dash_prof = dashboard_stats.get('profitability_completed', {}).
6. Calls compare(...) for its side effect.
7. Calls compare(...) for its side effect.
8. Calls compare(...) for its side effect.
9. Calls compare(...) for its side effect.
10. Calls compare(...) for its side effect.
11. Assigns local_cash = local_stats.get('cashflow_inprogress', {}).
12. Assigns dash_cash = dashboard_stats.get('cashflow_inprogress', {}).
13. Calls compare(...) for its side effect.
14. Calls compare(...) for its side effect.
15. ... and 15 more statement(s) in the body.

Code (copy-paste safe)

```
def verify_stats(self, local_stats, dashboard_stats):

```

Method: TradeOpssAIApp.auto_push_loop

```
def auto_push_loop(self)
```

Background loop for smart auto-pushing.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns cycle = 0.
2. **while** self.auto_push_enabled: loops until the condition is false.

Code (copy-paste safe)

```
def auto_push_loop(self):
    """Background loop for smart auto-pushing."""
    cycle = 0
    while self.auto_push_enabled:
        try:
            self.root.after(0, self.check_and_push_update)
        except Exception as e:
            # Thread-safe: can't call self.log from background thread directly
            try:
                self.root.after(0, lambda err=str(e): self.log(f"■ Auto-push loop error: {err}", "ERR"))
            except Exception:
                pass

                self.root.after(0, lambda c=cycle: self.log(
                    f"■ Auto-push heartbeat (cycle {c}) - watching for new trades"))
            except Exception:
                pass
```

Method: TradeOpssAIApp._build_trading_engine_ui

```
def _build_trading_engine_ui(self, parent)
```

Build the Trading Engine section with CTK styled cards.

Why these Python concepts were used

- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns mt5_card = self._section_card(parent, 'MT5 CONNECTION', '■').
2. Calls mt5_card.pack(...) for its side effect.
3. Assigns mt5_row = ctk.CTkFrame(mt5_card, fg_color='transparent') if CTK_AVA....
4. Calls mt5_row.pack(...) for its side effect.
5. **if** CTK_AVAILABLE: branches conditionally.
6. Assigns self.mt5_login = self._ctk_entry(mt5_row, width=120).
7. Calls self.mt5_login.pack(...) for its side effect.
8. **if** CTK_AVAILABLE: branches conditionally.

9. Assigns `self.mt5_password = self._ctk_entry(mt5_row, width=120, show='*')`.
10. Calls `self.mt5_password.pack(...)` for its side effect.
11. `if CTK_AVAILABLE:` branches conditionally.
12. Assigns `self.mt5_server = self._ctk_entry(mt5_row, width=160)`.
13. Calls `self.mt5_server.pack(...)` for its side effect.
14. Assigns `mt5_btn_row = ctk.CTkFrame(mt5_card, fg_color='transparent')` if `CTK_AVA...`
15. ... and 35 more statement(s) in the body.

```

Method: TradeOpssAIApp._resolve_starting_balance

```
def _resolve_starting_balance(self, ev, current_phase, acct_size)
```

Return the firm-correct starting balance for profit math. For Funded / Payout phases on firms whose funded balance starts at \$0 (MFFU family), this returns 0 instead of the challenge size. All other firms / phases fall back to the challenge size parsed from acct_size.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't

have to handle it.

- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns `start_str = str(acct_size or "").replace('$', "").replace(',', ' ').strip().lower()`
2. `if start_str.endswith('k')`: branches conditionally (with an **else/elif** arm).
3. Assigns `funded_phases = ('Funded', 'Payout 1', 'Payout 2', 'Payout 3', 'Payout 4')`
4. `if current_phase not in funded_phases`: branches conditionally.
5. Assigns `firm_raw = (ev or {}).get('Prop Firm', '')` if `isinstance(ev, dict)` else...
6. Assigns `canonical = self._FIRM_MAP.get(firm_raw, firm_raw)`.
7. Assigns `mode = self._FUNDED_START_BALANCE_MODE.get(canonical, 'ACCOUNT_SIZE')`
8. `if mode == 'ZERO'`: branches conditionally.
9. **return** `default_start`.

Code (copy-paste safe)

```
def _resolve_starting_balance(self, ev, current_phase, acct_size):
    """Return the firm-correct starting balance for profit math.

    For Funded / Payout phases on firms whose funded balance starts at $0
    (MFFU family), this returns 0 instead of the challenge size. All other
    firms / phases fall back to the challenge size parsed from acct_size.
    """
    # Parse acct_size as the default
    start_str = str(acct_size or '').replace("$", "").replace(",", "").strip().lower()
    if start_str.endswith("k"):
        try:
            default_start = float(start_str[:-1]) * 1000
        except ValueError:
            default_start = 50000.0
    elif start_str.replace(".", "").isdigit():
        default_start = float(start_str)
    else:
        default_start = 50000.0

    # Only Funded / Payout / Double Dip phases differ from challenge size
    funded_phases = ("Funded", "Payout 1", "Payout 2", "Payout 3", "Payout 4", "Double Dip")
    if current_phase not in funded_phases:
        return default_start

    firm_raw = (ev or {}).get("Prop Firm", "") if isinstance(ev, dict) else ""
    canonical = self._FIRM_MAP.get(firm_raw, firm_raw)
    mode = self._FUNDED_START_BALANCE_MODE.get(canonical, "ACCOUNT_SIZE")

        return 0.0
    return default_start
```

Method: TradeOpssAIApp._detect_eval_phase

```
def _detect_eval_phase(self, ev)
```

Determine current phase display name and blueprint key for an evaluation.

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `challenge_status = (ev.get('Status P1', '') or '').strip().lower()`.
2. Assigns `funded_status = (ev.get('Status', '') or '').strip().lower()`.
3. Assigns `has_funded_acct = bool((ev.get('Account #.1', '') or '').strip())`.
4. Assigns `has_farming_marker = bool((ev.get('Prop Day 1', '') or '').strip())`.
5. Assigns `has_hedge_day_data = False`.
6. **if** `has_farming_marker`: branches conditionally.
7. **if** `has_farming_marker` and `has_hedge_day_data`: branches conditionally (with an **else/elif** arm).

Code (copy-paste safe)

```
def _detect_eval_phase(self, ev):
    """Determine current phase display name and blueprint key for an evaluation."""
    challenge_status = (ev.get("Status P1", "") or "").strip().lower()
    funded_status = (ev.get("Status", "") or "").strip().lower()
    has_funded_acct = bool((ev.get("Account #.1", "") or "").strip())

    # Check if farming data exists – must have BOTH the farming marker
    # AND actual Hedge Day cell data for THIS account (not just sheet columns)
    has_farming_marker = bool((ev.get("Prop Day 1", "") or "").strip())
    has_hedge_day_data = False
    if has_farming_marker:
        for i in range(1, 35):
            val = (ev.get(f"Hedge Day {i}", "") or "").strip()
            if val and val not in ("-", "-"):
                has_hedge_day_data = True
                break

    if has_farming_marker and has_hedge_day_data:
        return "Farming", "farming"
    elif has_funded_acct and funded_status not in self._FAILED_STATUSES:
        return "Funded", "funded_trade1"
    else:
        return "Challenge", "challenge_trade1"
```

Method: TradeOpssAIApp._resolve_phase_key_from_day

```
def _resolve_phase_key_from_day(self, ev, firm_code, current_phase)
```

Use the day placeholder cell index to determine the correct blueprint key. The day placeholder position (0-based) maps directly to the trade order in `_PHASE_TRADE_ORDER`. E.g. cell index 2 → third trade in the sequence. Scans all field sets if the detected phase has no day placeholder, and corrects the phase accordingly. Returns (resolved_phase_key, day_index, day_name) or (None, None, None) if no day placeholder is found.

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns (day_idx, day_name, is_today, matched_phase) = self._find_tradeable_day_cell(ev, current_phase).
2. **if** day_idx is None: branches conditionally.
3. Assigns effective_phase = matched_phase if matched_phase else current_phase.
4. **if** matched_phase and matched_phase != current_phase: branches conditionally.
5. **if** not self.prop_firm_mgr: branches conditionally.
6. Assigns phase_map = {'Challenge': 'Challenge', 'Funded': 'Funded', 'Farming':....
7. Assigns phase_group = phase_map.get(effective_phase, effective_phase).
8. Assigns firm_orders = self.prop_firm_mgr._PHASE_TRADE_ORDER.get(firm_code, {}).
9. Assigns trade_keys = firm_orders.get(phase_group, []).
10. **if** not trade_keys: branches conditionally.
11. Assigns key_idx = min(day_idx, len(trade_keys) - 1).
12. Assigns resolved_key = trade_keys[key_idx].
13. **return** (resolved_key, day_idx, day_name).

Code (copy-paste safe)

```
def _resolve_phase_key_from_day(self, ev, firm_code, current_phase):
    """Use the day placeholder cell index to determine the correct blueprint key.

if not trade_keys:
    return None, day_idx, day_name

# Clamp day index to available trade keys
key_idx = min(day_idx, len(trade_keys) - 1)
resolved_key = trade_keys[key_idx]
return resolved_key, day_idx, day_name

```

Method: TradeOpssAIApp._parse_day_token

```

@classmethod
def _parse_day_token(cls, value)

    Extract a weekday number (0=Mon..6=Sun) from a cell value. Lenient parsing that handles surrounding
    punctuation, extra text, and embedded day names (e.g. ``"MONDAY ✓"`, ``"Mon-04/27"`, ``"Mon -
    waiting"``). Returns the weekday number or ``None``.

```

Why these Python concepts were used

- **@classmethod** — Marked **@classmethod** — receives the class itself as the first argument. The standard pattern for alternate constructors that build an instance from a different input shape (e.g., from a dict, a CSV row, or an MT5 order tuple).
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

Step by step (top-level body)

1. **if** value is None: branches conditionally.
2. **try** block with 1 **except** clause.
3. **if not s**: branches conditionally.
4. **if s in cls._DAY_ABBREVS**: branches conditionally.
5. Imports **re** (lazy import inside the function).
6. **for tok in _re.split('[\s\\-/,:;\.]+', s)**: iterates.
7. **return None**.

Code (copy-paste safe)

```

def _parse_day_token(cls, value):
    """Extract a weekday number (0=Mon..6=Sun) from a cell value.

    Lenient parsing that handles surrounding punctuation, extra text,
    and embedded day names (e.g. ``"MONDAY ✓"`, ``"Mon-04/27"`,
    ``"Mon - waiting"``). Returns the weekday number or ``None``.

```

```

"""
if value is None:
    return None
try:
    s = str(value).strip().lower()
except Exception:
    return None
if not s:
    return None
# Whole-string match first
if s in cls._DAY_ABBREVS:
    return cls._DAY_ABBREVS[s]
# Tokenise on common separators (whitespace, hyphen, slash, comma, colon)
import re as _re
for tok in _re.split(r"[\s\-/,:;\.]+", s):
    tok = tok.strip()
    if tok in cls._DAY_ABBREVS:
        return cls._DAY_ABBREVS[tok]
return None

```

Method: TradeOpssAIApp._get_phase_fields

```
def _get_phase_fields(self, current_phase)
```

Return the ordered list of eval field names for a phase.

Why these Python concepts were used

- **list comprehension** — Builds a list in a single expression ([f(x) for x in xs]). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **if** current_phase == 'Challenge': branches conditionally (with an **else/elif** arm).
2. **return []**.

Code (copy-paste safe)

```

def _get_phase_fields(self, current_phase):
    """Return the ordered list of eval field names for a phase."""
    if current_phase == "Challenge":
        return [f"Hedge Result {i}" for i in range(1, 6)]
    elif current_phase in ("Funded", "Payout 1", "Payout 2", "Payout 3", "Payout 4"):
        return [f"Hedge Result {i}.1" for i in range(1, 8)]
    elif current_phase == "Double Dip":
        return [f"Hedge Result {i}.1" for i in range(1, 8)]
    elif current_phase == "Farming":
        return [f"Hedge Day {i}" for i in range(1, 35)]
    return []

```

Method: TradeOpssAIApp._count_completed_trades

```
def _count_completed_trades(self, ev, current_phase)
```

*Count how many trading day cells are filled for the current phase. A filled cell = a trade already taken.
Empty/blank = not yet traded. Day-name placeholders (MON, TUE, etc.) are NOT counted as completed.*

Returns (completed_count, total_fields, next_empty_index). next_empty_index is 0-based: the position of the first empty cell.

Why these Python concepts were used

- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns fields = self._get_phase_fields(current_phase).
2. Assigns completed = 0.
3. Assigns next_empty = None.
4. **for** (i, f) in enumerate(fields): iterates.
5. **if** next_empty is None: branches conditionally.
6. **return** (completed, len(fields), next_empty).

Code (copy-paste safe)

```
def _count_completed_trades(self, ev, current_phase):
    """Count how many trading day cells are filled for the current phase.

```

Method: TradeOpssAIApp._get_current_phase_profit

```
def _get_current_phase_profit(self, ev, current_phase, broker_account=None, acct_size=None)
```

Get the current P/L for the active phase. Priority: 1. Live broker equity (equity - starting balance) — most accurate 2. Eval hedge result fields — fallback when broker not available

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression ([f(x) for x in xs]). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. `if broker_account` and `acct_size`: branches conditionally.
2. Assigns `total = 0.0`.
3. Assigns `fields = []`.
4. `if current_phase == 'Challenge'`: branches conditionally (with an **else/elif** arm).
5. `for f in fields`: iterates.
6. **return** `total`.

Code (copy-paste safe)

```

    return phases[current_idx + 1]
```

Method: TradeOpssAIApp._is_eval_active

```
def _is_eval_active(self, ev)
```

Check if an evaluation is active (not failed/ended/deleted). Uses substring matching so 'Fail', 'Failed', 'Breached' etc. all caught.

Why these Python concepts were used

- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns `p1 = (ev.get('Status P1', '') or '').strip().lower()`.
2. Assigns `funded = (ev.get('Status', '') or '').strip().lower()`.
3. Assigns `has_funded_acct = bool((ev.get('Account #.1', '') or '').strip())`.
4. Assigns `has_challenge_acct = bool((ev.get('Account #', '') or '').strip())`.
5. Assigns `p1_inactive = any((kw in p1 for kw in self._INACTIVE_KEYWORDS)) if p1 else ...`
6. Assigns `funded_inactive = any((kw in funded for kw in (*self._INACTIVE_KEYWORDS, 'c...'`
7. **if** `p1_inactive` and `(not has_funded_acct)`: branches conditionally.
8. **if** `funded_inactive`: branches conditionally.
9. **if** `p1_inactive` and `has_funded_acct` and `funded_inactive`: branches conditionally.
10. **if** `not has_challenge_acct` and `(not has_funded_acct)`: branches conditionally.
11. **return** `True`.

Code (copy-paste safe)

```

```

Method: TradeOpssAIApp._load_active_trades

```
def _load_active_trades(self)
```

Fetch evaluations from dashboard and populate the active trades list.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.

Step by step (top-level body)

1. Assigns email = self.client_email_entry.get().strip().
2. Assigns dashboard_url = self.url_entry.get().strip().rstrip('/').
3. **if** not email: branches conditionally.
4. Calls self.log(...) for its side effect.
5. Calls self.load_trades_btn.configure(...) for its side effect.
6. Calls self.trades_count_var.set(...) for its side effect.
7. Defines a nested function _do_load(...).
8. Calls threading.Thread(target=_do_load, daemon=True).start(...) for its side effect.

Code (copy-paste safe)

```

def _load_active_trades(self):

```

Method: TradeOpssAIApp._eval_has_payout

```
def _eval_has_payout(self, ev)
```

Check if any hedge result field contains 'payout' text.

Why these Python concepts were used

- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.

Step by step (top-level body)

1. **if not ev:** branches conditionally.
2. **for (key, val) in ev.items():** iterates.
3. **return False.**

Code (copy-paste safe)

```
def _eval_has_payout(self, ev):
    """Check if any hedge result field contains 'payout' text."""
    if not ev:
        return False
    for key, val in ev.items():
        if "hedge result" in key.lower() and isinstance(val, str) and "payout" in val.lower():
            return True
    return False
```

Method: TradeOpssAIApp._execute_row_trade

```
def _execute_row_trade(self, side, row_data)
```

Execute a trade for a specific row, then remove the row.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to `sum`, `any`, `all`, or `max` where the intermediate list would be wasted.
- **lambda** — Uses a single-expression anonymous function — typically as the `key=` for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

- **raise** — Raises an exception explicitly. Either signals an invalid argument the caller should fix, or re-raises after logging.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **walrus operator (:=)** — Assigns and tests in one expression — typically inside a while or if to capture a regex match or a non-None lookup without an extra line.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns `ev = row_data.get('eval', {})`.
2. `if self._eval_has_payout(ev):` branches conditionally.
3. Assigns `direction = self.direction_var.get()`.
4. `if direction == 'Buy Only' and side == 'sell':` branches conditionally.
5. `if direction == 'Sell Only' and side == 'buy':` branches conditionally.
6. Assigns `firm_code = row_data['firm_code']`.
7. Assigns `phase_key = row_data['phase_key']`.
8. Assigns `acct_size = row_data['acct_size']`.
9. Assigns `acct_num = row_data['acct_num']`.
10. Assigns `fresh_ev = self._refresh_eval_for_account(acct_num)`.
11. `if fresh_ev:` branches conditionally.
12. Assigns `(resolved_key, day_idx, day_name) = self._resolve_phase_key_from_day(ev, firm_code, row_data[...]`
13. `if resolved_key is None:` branches conditionally.
14. `if resolved_key != phase_key:` branches conditionally.
15. ... and 38 more statement(s) in the body.

```

Method: TradeOpssAIApp._test_min_equity

```
def _test_min_equity(self, event=None)
```

Test: dump min equity data from cached prop firm mappings and Tradovate API.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Calls self.log(...) for its side effect.
2. **if** self._cached_acct_mappings: branches conditionally (with an **else/elif** arm).
3. Assigns found = False.
4. **for** (firm_name, conn) in self._broker_connections.items(): iterates.
5. **if** not found: branches conditionally.

6. Calls `self.log(...)` for its side effect.

Code (copy-paste safe)

```
def _test_min_equity(self, event=None):
    """Test: dump min equity data from cached prop firm mappings and Tradovate API."""
    self.log("■ Testing min equity sources...")
    # 1. Cached prop firm mappings

```

Method: `TradeOpssAIApp._start_hedge_protector`

```
def _start_hedge_protector(self)
```

Start (or restart) the Hedge Protector engine. Called automatically on broker connect.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **lambda** — Uses a single-expression anonymous function — typically as the `key=` for a sort, the filter predicate, or a small callback.

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **if** `RELEASE_DISABLE_HEDGE_GUARD`: branches conditionally.
2. **if** `not HEDGE_PROTECTOR_AVAILABLE`: branches conditionally.

```

Method: TradeOpssAIApp._handle_hedge_status_change

```
def _handle_hedge_status_change(self, acct_name, close_reason, phase_key)
```

Update dashboard status immediately when TP/SL detected by hedge protector. Args: acct_name: Tradovate account name (e.g. "FNFTCHHARRISONOUKA85625") close_reason: "tp_detected" or "sl_detected" phase_key: Blueprint stage key from MT5 comment (e.g. "challenge_trade2", "funded_trade1")

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression ([f(x) for x in xs]). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **if** RELEASE_DISABLE_AUTO_STATUS_UPDATES: branches conditionally.
2. Imports re (lazy import inside the function).
3. Assigns matched_ev = None.
4. Assigns matched_rd = None.
5. Assigns acct_lower = acct_name.lower().
6. **for** rd in self._active_trade_rows: iterates.
7. **if** not matched_ev: branches conditionally.
8. Assigns has_funded = bool((matched_ev.get('Account #.1') or "").strip()).
9. Assigns status_field = 'Status' if has_funded else 'Status P1'.
10. **if** close_reason == 'sl_detected': branches conditionally (with an **else/elif** arm).
11. Assigns current_status = (matched_ev.get(status_field) or "").strip().
12. **if** current_status.lower() == new_status.lower(): branches conditionally.
13. Assigns matched_ev[status_field] = new_status.
14. Calls self.log(...) for its side effect.
15. ... and 9 more statement(s) in the body.

Liquidate all positions across every connected broker and MT5.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression ([f(x) for x in xs]). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **raise** — Raises an exception explicitly. Either signals an invalid argument the caller should fix, or re-raises after logging.

- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns `connected = [f for f, c in self._broker_connections.items() if c.get(...]`
2. `if not connected:` branches conditionally.
3. `if not messagebox.askyesno('Close ALL Trades', f'This will LIQUIDATE a...:` branches conditionally.
4. Calls `self.log(...)` for its side effect.
5. Calls `self._add_activity(...)` for its side effect.
6. Defines a nested function `_do_close_all(...)`.
7. Calls `threading.Thread(target=_do_close_all, daemon=True, name='CloseAll').start(...)` for its side effect.

    hours, rem = divmod(int(remaining.total_seconds()), 3600)
    minutes, seconds = divmod(rem, 60)
    self.auto_trade_countdown_var.set(f"Starts in {hours}h {minutes}m {seconds}s")
    self.root.after(1000, self._tick_auto_trade_countdown)

```

Method: TradeOpssAIApp._auto_trade_loop

```
def _auto_trade_loop(self)
```

Background thread: wait until scheduled time, then execute all trades.

Why these Python concepts were used

- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.

Step by step (top-level body)

1. Lazy import from datetime.
2. Assigns EAT = timezone(timedelta(hours=3)).
3. **while** self.auto_trade_enabled and (not self._auto_trade_stop.is_set()): loops until the condition is false.

Code (copy-paste safe)

```
def _auto_trade_loop(self):
    """Background thread: wait until scheduled time, then execute all trades."""
    from datetime import datetime, timedelta, timezone
    EAT = timezone(timedelta(hours=3))

    while self.auto_trade_enabled and not self._auto_trade_stop.is_set():
        now = datetime.now(EAT)
        if now >= self._auto_trade_scheduled_dt:
            # Time to execute
            self.root.after(0, lambda: self.auto_trade_countdown_var.set("Executing now..."))
            self.root.after(0, self._auto_execute_all_trades)
            return
        # Sleep 1 second between checks
        self._auto_trade_stop.wait(timeout=1)
```

Method: TradeOpssAIApp._auto_execute_all_trades

```
def _auto_execute_all_trades(self)
```

Execute trades for ALL loaded rows, parallel across prop firms. Each prop firm has its own Chrome instance opened during initialization. Trades for different firms run in parallel threads (one thread per firm), while trades for the same firm run sequentially within that thread.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **list comprehension** — Builds a list in a single expression ([f(x) for x in xs]). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **dict comprehension** — Builds a dict in one expression ({k: v for k, v in items}) — same intent as a list comprehension but for mappings.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.

- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **raise** — Raises an exception explicitly. Either signals an invalid argument the caller should fix, or re-raises after logging.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns `firm_sides = getattr(self, '_auto_trade_firm_sides', {})`.
2. Assigns `use_signal = getattr(self, '_auto_trade_use_signal', False)`.
3. Assigns `rows = list(self._active_trade_rows)`.
4. `if not rows:` branches conditionally.
5. Calls `self.log(...)` for its side effect.
6. Assigns `hedging = self.hedge_mode_var.get() == 'Hedging'`.
7. Assigns `default_platform = self.broker_var.get()`.
8. Assigns `mt5_api = self._get_mt5_trading_api()` if hedging else `None`.
9. `if hedging and (not mt5_api):` branches conditionally.
10. Assigns `rows_by_firm = defaultdict(list)`.
11. `for row_data in rows:` iterates.
12. Assigns `payout_skipped = []`.
13. `for (firm_name, firm_rows) in list(rows_by_firm.items()):` iterates.
14. `if payout_skipped:` branches conditionally.
15. ... and 8 more statement(s) in the body.

Code (copy-paste safe)

```

Method: TradeOpssAIApp._populate_broker_rows

```
def _populate_broker_rows(self, evaluations, prop_accounts)

    Build one connection row per unique prop firm from active evaluations.
```

Why these Python concepts were used

- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **for** child in self._broker_rows_frame.wininfo_children(): iterates.
2. Assigns old_connections = dict(self._broker_connections).
3. Calls self._broker_connections.clear(...) for its side effect.
4. Assigns firms = [].
5. Assigns seen = set().
6. **for** ev in evaluations: iterates.
7. **if** not firms: branches conditionally.
8. **if** CTK_AVAILABLE: branches conditionally.
9. Assigns pa_lookup = {}.
10. Assigns pa_unmatched = [].
11. **for** pa in prop_accounts or []: iterates.
12. **if** prop_accounts: branches conditionally.
13. Assigns auto_count = 0.
14. **for** firm in firms: iterates.
15. ... and 1 more statement(s) in the body.

Code (copy-paste safe)

```
def _populate_broker_rows(self, evaluations, prop_accounts):
    """Build one connection row per unique prop firm from active evaluations."""
    for child in self._broker_rows_frame.wininfo_children():

Method: TradeOpssAIApp._connect_broker_firm

```
def _connect_broker_firm(self, firm_name)
```

Connect a single prop firm's broker account.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.

Step by step (top-level body)

1. Assigns conn = self._broker_connections.get(firm_name).
2. **if** not conn: branches conditionally.
3. Assigns firm_lower = firm_name.lower().
4. **if** 'topstep' in firm_lower: branches conditionally (with an **else/elif** arm).
5. Assigns user = conn['user_entry'].get().strip().
6. Assigns pwd = conn['pass_entry'].get().strip().
7. Assigns mode = self.trading_mode_var.get().
8. **if** not user or not pwd: branches conditionally.
9. Calls self.log(...) for its side effect.
10. Calls conn['status_var'].set(...) for its side effect.
11. Calls conn['connect_btn'].configure(...) for its side effect.
12. Defines a nested function _do_connect(...).
13. Calls threading.Thread(target=_do_connect, daemon=True).start(...) for its side effect.

Code (copy-paste safe)

            time.sleep(3) # stagger to avoid overwhelming

    threading.Thread(target=_do_auto, daemon=True).start()

```

Method: TradeOpssAIApp._show_trade_history

```
def _show_trade_history(self, firm_name)
```

Show a popup window with full Tradovate trade history for the given firm.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.

Step by step (top-level body)

1. Assigns `conn = self._broker_connections.get(firm_name)`.
2. `if not conn or not conn.get('account')`: branches conditionally.
3. Assigns `account = conn['account']`.
4. `if not hasattr(account, 'get_trade_history')`: branches conditionally.
5. Calls `self.log(...)` for its side effect.
6. Defines a nested function `_fetch_and_show(...)`.
7. Calls `threading.Thread(target=_fetch_and_show, daemon=True).start(...)` for its side effect.

Code (copy-paste safe)

```

def _show_trade_history(self, firm_name):
    """Show a popup window with full Tradovate trade history for the given firm."""
    conn = self._broker_connections.get(firm_name)
    if not conn or not conn.get("account"):
        self.log(f"■ {firm_name} is not connected – connect first", "WARN")
    return

```

```

account = conn["account"]
if not hasattr(account, 'get_trade_history'):
    self.log(f"■ {firm_name} account does not support trade history", "WARN")
    return

self.log(f"■ Loading trade history for {firm_name}...")

def _fetch_and_show():

        self.root.after(0, lambda d=data: self._build_history_window(firm_name, d))
    except Exception as e:
        self.root.after(0, lambda: self.log(f"■ History fetch failed: {e}", "ERROR"))

threading.Thread(target=_fetch_and_show, daemon=True).start()

```

Method: TradeOpssAIApp._build_history_window

```
def _build_history_window(self, firm_name, data)
```

Build and display the trade history popup window. data is a list of account dicts (one per account under this login).

Why these Python concepts were used

- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. `if isinstance(data, dict):` branches conditionally.
2. Assigns `win = tk.Toplevel(self.root)`.
3. Assigns `acct_count = len(data)`.
4. Calls `win.title(...)` for its side effect.

```

Method: TradeOpssAIApp._auto_launch_propfirm_browsers

```
def _auto_launch_propfirm_browsers(self, active_firms)
```

Detect which active prop firms have browser-based dashboards and store them so the UI dashboard buttons know what to launch. Does NOT auto-open browsers — the user clicks the "Dashboard" button in the broker row. Tradovate/TopStepX auto-connect with credentials as before.

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. if RELEASE_DISABLE_PROP_DASHBOARD_ACCESS: branches conditionally.

2. **for** `firm` in `active_firms`: iterates.

Code (copy-paste safe)

```
def _auto_launch_propfirm_browsers(self, active_firms):
    """
    Detect which active prop firms have browser-based dashboards and store
    them so the UI dashboard buttons know what to launch. Does NOT auto-open
    browsers – the user clicks the "Dashboard" button in the broker row.
    Tradovate/TopStepX auto-connect with credentials as before.
    """
    if RELEASE_DISABLE_PROP_DASHBOARD_ACCESS:
        return

    for firm in active_firms:

        if not cfg:
            continue
        class_avail = globals().get(cfg["class_available"], False)
        if class_avail:
            self.log(f"■ {firm} has a dashboard – click the Dashboard button to connect")
```

Method: `TradeOpssAIApp._launch_propfirm_dashboard`

```
def _launch_propfirm_dashboard(self, firm_name)
```

Launch a Chrome browser for the prop firm's dashboard, show login dialog. Called when user clicks the 'Dashboard' button in a broker row. For CDP-based scrapers, attaches to an existing Chrome tab instead of launching new Chrome.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.

Step by step (top-level body)

1. **if** `RELEASE_DISABLE_PROP_DASHBOARD_ACCESS`: branches conditionally.
2. Assigns `cfg = self._BROWSER_MONITORED_FIRMS.get(firm_name)`.
3. **if** `not cfg`: branches conditionally.
4. **if** `not cfg`: branches conditionally.
5. **if** `firm_name` in `self._propfirm_browsers` and `self._propfirm_browsers[fi...]`: branches conditionally.
6. Assigns `class_avail = globals().get(cfg['class_available'], False)`.
7. **if** `not class_avail`: branches conditionally.

8. if `cfg.get('cdp')`: branches conditionally.

Code (copy-paste safe)

```
def _launch_propfirm_dashboard(self, firm_name):
    """
    Launch a Chrome browser for the prop firm's dashboard, show login dialog.

```

Method: TradeOpssAIApp._on_cdp_login_confirmed

```
def _on_cdp_login_confirmed(self, firm_name, acct, cfg, dialog, status_var, confirm_btn)
```

Attach CDP after user confirms they've logged in.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.

Step by step (top-level body)

1. Calls `confirm_btn.configure(...)` for its side effect.
2. Calls `status_var.set(...)` for its side effect.
3. Defines a nested function `_attach(...)`.
4. Calls `threading.Thread(target=_attach, daemon=True).start(...)` for its side effect.

Code (copy-paste safe)

```
def _on_cdp_login_confirmed(self, firm_name, acct, cfg, dialog, status_var, confirm_btn):
    """Attach CDP after user confirms they've logged in."""
    confirm_btn.configure(state="disabled")
    status_var.set("■ Attaching to dashboard...")

    def _attach():
        try:
            login_url = cfg.get("login_url", "")
            acct.login(open_url=login_url)
            self._propfirm_browsers[firm_name] = acct
            self.root.after(0, lambda: self.log(
                f"■ {firm_name} dashboard connected via CDP"))
            acct_mapping = self._autofill_challenge_fees(firm_name, acct)
            self._cached_acct_mappings[firm_name] = acct_mapping or {}
            self._auto_detect_breached_accounts(firm_name, acct, acct_mapping=acct_mapping)
            self.root.after(0, dialog.destroy)
        except ConnectionError:
            self.root.after(0, lambda: status_var.set(
                f"■ Could not find {firm_name} tab.\n"
                f"Make sure {cfg.get('login_url', '')} is open and loaded.))
            self.root.after(0, lambda: confirm_btn.configure(state="normal"))
        except Exception as e:
            self.root.after(0, lambda err=str(e): status_var.set(f"■ {err}"))
            self.root.after(0, lambda: confirm_btn.configure(state="normal"))

    threading.Thread(target=_attach, daemon=True).start()
```

Method: TradeOpssAIApp._verify_propfirm_browser

```
def _verify_propfirm_browser(self, firm_name, account, cfg, dialog=None, status_var=None)
    Navigate to accounts page, verify login, auto-fill fees, close dialog.
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression ([f(x) for x in xs]). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Defines a nested function `_update_status(...)`.
2. Defines a nested function `_close_dialog(...)`.
3. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

```

Method: TradeOpssAIApp._autofill_challenge_fees

```
def _autofill_challenge_fees(self, firm_name, account)
```

Scrape billing history from the prop firm dashboard and auto-fill the 'Fee', 'Date Purchased', and 'Account #' fields of active evaluations. Then push the updated evaluations to the dashboard. For FundedNext Futures accounts, also resolves the billing login ID to the Tradovate account name (e.g. 945576089 -> FNFTCHHARRISONOUKA85625). Returns the acct_mapping dict (or {}) so callers can reuse it for breach detection.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression ([f(x) for x in xs]). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Method: TradeOpssAIApp._compute_firm_billing

```
def _compute_firm_billing(self, firm_name, account, billing)
```

Compute per-firm total fees and payouts from scraped billing + payout data. Returns (total_fees, total_payouts, records).

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.

Step by step (top-level body)

1. Assigns `total_fees = sum((e.get('paid_amount_numeric', 0.0) for e in billing i....`
2. Assigns `records = []`.
3. **for** `e in billing`: iterates.
4. Assigns `total_payouts = 0.0`.
5. **try** block with 1 **except** clause.
6. **return** `(total_fees, total_payouts, records)`.

Code (copy-paste safe)

```

def _compute_firm_billing(self, firm_name, account, billing):
    """Compute per-firm total fees and payouts from scraped billing + payout data.
    Returns (total_fees, total_payouts, records)."""
    total_fees = sum(
        e.get("paid_amount_numeric", 0.0)
        for e in billing
        if (e.get("status") or "").strip().upper() == "APPROVED"
        and e.get("paid_amount_numeric", 0) > 0
    )
    records = []
    for e in billing:
        if (e.get("status") or "").strip().upper() == "APPROVED" and e.get("paid_amount_numeric", 0) > 0:
            records.append({

```

Method: TradeOpssAIApp._start_status_polling

```
def _start_status_polling(self)
```

Start the 10-second real-time status polling loop. Uses Tradovate broker API to fetch live balances for all accounts.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.

Step by step (top-level body)

1. **if RELEASE_DISABLE_STATUS_POLL:** branches conditionally.
2. **if self._status_poll_active:** branches conditionally.
3. Assigns **self._status_poll_active = True**.
4. Calls **self.root.after(...)** for its side effect.
5. Defines a nested function **_first_poll(...)**.
6. Calls **threading.Thread(target=_first_poll, daemon=True).start(...)** for its side effect.
7. Calls **self.root.after(...)** for its side effect.

Code (copy-paste safe)

```

def _start_status_polling(self):
    """Start the 10-second real-time status polling loop.
    Uses Tradovate broker API to fetch live balances for all accounts."""

```

```

if RELEASE_DISABLE_STATUS_POLL:
    self._status_poll_active = False
    return

if self._status_poll_active:
    return # already running
self._status_poll_active = True
self.root.after(0, lambda: self.log("■ Status polling started (every 5 min)"))
# Run FIRST poll immediately, then schedule repeating every 5 min
def _first_poll():
    try:
        self._poll_tradovate_balances()
    except Exception as e:
        self.root.after(0, lambda err=str(e):
            self.log(f"■ First status poll error: {err}", "WARN"))
        threading.Thread(target=_first_poll, daemon=True).start()
    self.root.after(300_000, self._poll_account_status)

```

Method: TradeOpssAIApp._poll_account_status

```
def _poll_account_status(self)
```

Self-rescheduling timer — fetches Tradovate balances and updates P1 status.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.

Step by step (top-level body)

1. **if RELEASE_DISABLE_STATUS_POLL:** branches conditionally.
2. **if not self._status_poll_active:** branches conditionally.
3. Defines a nested function **_poll_all(...)**.
4. Calls **threading.Thread(target=_poll_all, daemon=True).start(...)** for its side effect.
5. Calls **self.root.after(...)** for its side effect.

Code (copy-paste safe)

```

def _poll_account_status(self):
    """Self-rescheduling timer — fetches Tradovate balances and updates P1 status."""
    if RELEASE_DISABLE_STATUS_POLL:
        return

    if not self._status_poll_active:
        return

```

```

def _poll_all():
    try:
        self._poll_tradovate_balances()
    except Exception as e:
        self.root.after(0, lambda err=str(e):
            self.log(f"■ Status poll error: {err}", "WARN"))

threading.Thread(target=_poll_all, daemon=True).start()
self.root.after(300_000, self._poll_account_status)

```

Method: TradeOpssAIApp._poll_tradovate_balances

```
def _poll_tradovate_balances(self)
```

Fetch live balances from Tradovate broker API and update P1/Status on evaluations.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **dict comprehension** — Builds a dict in one expression (`{k: v for k, v in items}`) — same intent as a list comprehension but for mappings.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to `sum`, `any`, `all`, or `max` where the intermediate list would be wasted.
- **lambda** — Uses a single-expression anonymous function — typically as the `key=` for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **if** `RELEASE_DISABLE_STATUS_POLL`: branches conditionally.
2. Assigns `tv_balances = {}`.
3. **for** `(firm_name, conn)` in `list(self._broker_connections.items())`: iterates.
4. **if not** `tv_balances`: branches conditionally.
5. **if not** `hasattr(self, '_poll_logged_tv_accounts')`: branches conditionally.
6. Assigns `tv_lower = {k.lower(): (k, v) for k, v in tv_balances.items()}`.
7. Assigns `email = self.client_email_entry.get().strip()`.
8. Assigns `dashboard_url = self.url_entry.get().strip().rstrip('/')`.
9. **if not** `email` or `not dashboard_url`: branches conditionally.
10. **try** block with 1 **except** clause.

11. Assigns `self._poll_dashboard_err_logged = False`.

12. `if not all_evals:` branches conditionally.

13. Assigns `any_changed = False`.

14. `for ev in all_evals:` iterates.

15. ... and 3 more statement(s) in the body.

Code (copy-paste safe)

Method: TradeOpssAIApp._auto_detect_breached_accounts

```
def _auto_detect_breached_accounts(self, firm_name, account, acct_mapping=None)
```

Check if any evaluations have been breached on FundedNext and auto-set their status to 'Failed' with the breach reason. Uses the account mapping (from get_account_mapping) which includes breach status from the React fiber, plus optionally the account-overview API for detailed breach info (breach reason, reset price etc). Fetches ALL evaluations from the dashboard (not just _active_trade_rows) since breached accounts may already be filtered out of the active rows.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression ([f(x) for x in xs]). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

```

Method: TradeOpssAIApp._get_mt5_trading_api

```
def _get_mt5_trading_api(self)
```

Get or create the MT5 trading API from companion's existing MT5 connection.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **if** self.trading_api and hasattr(self.trading_api, 'is_connected') and ...: branches conditionally.
2. Assigns login = self.mt5_login.get().strip().
3. Assigns pwd = self.mt5_password.get().strip().
4. Assigns server = self.mt5_server.get().strip().
5. **if** login and pwd and server: branches conditionally.
6. **return** None.

Code (copy-paste safe)

```

def _get_mt5_trading_api(self):

            return True
        self.log(f"■ MT5 auto-connect failed: {msg}", "WARN")
    return False
```

Method: TradeOpssAIApp._get_daily_bias

```
def _get_daily_bias(self, firms)
```

Get or create today's direction bias per prop firm. Persisted to trader_bias.json so it survives app restarts. Resets automatically on a new calendar day (EAT).

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **dict comprehension** — Builds a dict in one expression (`{k: v for k, v in items}`) — same intent as a list comprehension but for mappings.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to `sum`, `any`, `all`, or `max` where the intermediate list would be wasted.

Step by step (top-level body)

1. Lazy import from `datetime`.
2. Assigns `EAT = timezone(timedelta(hours=3))`.
3. Assigns `today_str = datetime.now(EAT).strftime('%Y-%m-%d')`.
4. Assigns `bias_path = os.path.join(os.path.dirname(__file__), 'trader_bias.json')`.
5. Assigns `saved = {}`.
6. **if** `os.path.exists(bias_path)`: branches conditionally.
7. **if** `saved.get('date') != today_str`: branches conditionally.
8. Assigns `firm_bias = saved.get('firms', {})`.
9. Assigns `changed = False`.
10. **for** `firm in sorted(firms)`: iterates.
11. **if** `changed or saved.get('date') != today_str`: branches conditionally.
12. **return** `{f: firm_bias[f] for f in firms}`.

Code (copy-paste safe)

```
def _get_daily_bias(self, firms):

```

Method: TradeOpssAIApp._get_indicator_map

```

@classmethod
def _get_indicator_map(cls)

    Build indicator map lazily (needs imports to be resolved).

```

Why these Python concepts were used

- **@classmethod** — Marked **@classmethod** — receives the class itself as the first argument. The standard pattern for alternate constructors that build an instance from a different input shape (e.g., from a dict, a CSV row, or an MT5 order tuple).
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

Step by step (top-level body)

1. if `cls._SIGNAL_INDICATORS` is not `None`: branches conditionally.
2. Assigns `indicators = {}`.
3. **try** block with 1 **except** clause.
4. **try** block with 1 **except** clause.

5. **try** block with 1 **except** clause.
6. **try** block with 1 **except** clause.
7. **try** block with 1 **except** clause.
8. **try** block with 1 **except** clause.
9. **try** block with 1 **except** clause.
10. Assigns `cls._SIGNAL_INDICATORS = indicators`.
11. **return** indicators.

Code (copy-paste safe)

```
def _get_indicator_map(cls):

    except Exception:
        pass
    cls._SIGNAL_INDICATORS = indicators
    return indicators
```

Method: `TradeOpssAIApp._get_signal_direction`

```
def _get_signal_direction(self, mt5_symbol, timeframe=None, num_indicators=3)
```

Generate a trade direction by polling a random subset of indicators. Picks `num\_indicators` random indicators, queries each on the given MT5 symbol, and uses majority vote to decide buy vs sell. Falls back to random if no indicators produce a signal.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **if not MT5_AVAILABLE:** branches conditionally.
2. Assigns `mt5_mod = mt5`.
3. **if timeframe is None:** branches conditionally.
4. **if not mt5_mod.terminal_info():** branches conditionally.
5. Assigns `indicators = self._get_indicator_map()`.
6. **if not indicators:** branches conditionally.
7. Assigns `available = list(indicators.keys())`.
8. Assigns `pick_count = min(num_indicators, len(available))`.
9. Assigns `chosen = random.sample(available, pick_count)`.
10. Assigns `buy_votes = 0`.
11. Assigns `sell_votes = 0`.
12. Assigns `details = []`.
13. **for name in chosen:** iterates.
14. Assigns `detail_str = ', '.join(details)`.
15. ... and 3 more statement(s) in the body.

Code (copy-paste safe)

```
def _get_signal_direction(self, mt5_symbol, timeframe=None, num_indicators=3):
    """Generate a trade direction by polling a random subset of indicators.

    Picks `num_indicators` random indicators, queries each on the given
    MT5 symbol, and uses majority vote to decide buy vs sell.
    Falls back to random if no indicators produce a signal.
    """
    if not MT5_AVAILABLE:
        self.root.after(0, lambda: self.log("■ MetaTrader5 import unavailable – using random direction",
            "WARN"))
        return random.choice(["buy", "sell"])
    mt5_mod = mt5
    if timeframe is None:

return direction

```

Method: TradeOpssAIApp.save_config

```
def save_config(self)

    Save configuration to file.
```

Why these Python concepts were used

- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. Assigns `config = {'dashboard_url': self.url_entry.get(), 'client_email': s....`
2. `if hasattr(self, 'broker_var')`: branches conditionally.
3. Assigns `config_path = os.path.join(os.path.dirname(__file__), 'trader_config.js....`
4. `with open(config_path, 'w')`: enters a context manager.
5. Calls `self.log(...)` for its side effect.
6. Calls `messagebox.showinfo(...)` for its side effect.

Code (copy-paste safe)

```
def save_config(self):
    """Save configuration to file."""
    config = {
        "dashboard_url": self.url_entry.get(), # Save dynamic URL
        "client_email": self.client_email_entry.get(),
        "sheet_url": self.sheet_url_entry.get(),
        "mt5_login": self.mt5_login.get(),
        "mt5_server": self.mt5_server.get()
    }
    # Trading engine settings
    if hasattr(self, 'broker_var'):
        config["broker_platform"] = self.broker_var.get()
        config["trading_mode"] = self.trading_mode_var.get()
        config["prop_firm"] = self.prop_firm_var.get()
        config["phase"] = self.phase_var.get()
        config["account_size"] = self.acct_size_var.get()
        config["hedge_mode"] = self.hedge_mode_var.get()
        config["direction"] = self.direction_var.get()
        config["strategy"] = self.strategy_var.get()

    config_path = os.path.join(os.path.dirname(__file__), "trader_config.json")
    with open(config_path, 'w') as f:
        json.dump(config, f, indent=2)

    self.log("Configuration saved")
    messagebox.showinfo("Saved", "Configuration saved successfully")
```

Method: TradeOpssAIApp.load_config

```
def load_config(self)

    Load configuration from file.
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `config_path = os.path.join(os.path.dirname(__file__), 'trader_config.js....`
2. `if os.path.exists(config_path):` branches conditionally.

Code (copy-paste safe)

```
def load_config(self):
    """Load configuration from file."""
    config_path = os.path.join(os.path.dirname(__file__), "trader_config.json")
    if os.path.exists(config_path):
        try:
            with open(config_path, 'r') as f:
                config = json.load(f)

            # Do NOT load dashboard_url - keep hardcoded Trade0pps
            # saved_url = config.get('dashboard_url')
            # if saved_url:
            #     self.url_entry.delete(0, tk.END)
            #     self.url_entry.insert(0, saved_url)

            if config.get('client_email'):
                self.client_email_entry.delete(0, tk.END)

                self.sheet_url_entry.delete(0, tk.END)
                self.sheet_url_entry.insert(0, config.get('sheet_url', ''))

            if config.get('mt5_login'):
                self.mt5_login.delete(0, tk.END)
                self.mt5_login.insert(0, config.get('mt5_login', ''))

            if config.get('mt5_server'):
                self.mt5_server.delete(0, tk.END)
                self.mt5_server.insert(0, config.get('mt5_server', ''))

            # Trading engine settings
            if hasattr(self, 'broker_var'):
                if config.get('broker_platform'):
                    self.broker_var.set(config['broker_platform'])
                if config.get('trading_mode'):
                    self.trading_mode_var.set(config['trading_mode'])
                if config.get('prop_firm'):
                    self.prop_firm_var.set(config['prop_firm'])
                    self._on_prop_firm_change()
                if config.get('phase'):
                    self.phase_var.set(config['phase'])
                if config.get('account_size'):
                    self.acct_size_var.set(config['account_size'])
                if config.get('hedge_mode'):
                    self.hedge_mode_var.set(config['hedge_mode'])
                if config.get('direction'):
                    self.direction_var.set(config['direction'])
                if config.get('strategy'):
                    self.strategy_var.set(config['strategy'])
```

```

        self.log("Configuration loaded")
    except Exception as e:
        self.log(f"Failed to load config: {e}", "ERROR")

```

Method: TradeOpssAIApp.run

```
def run(self)

    Run the application.
```

Step by step (top-level body)

1. Calls `self.root.mainloop(...)` for its side effect.

Code (copy-paste safe)

```
def run(self):
    """Run the application."""
    self.root.mainloop()
```

Functions

```
def _gzip_post(url, payload, timeout=120, **kwargs)

    POST JSON payload compressed with gzip. Sends Content-Encoding: gzip so the server can decompress it. Falls back to normal JSON POST if compression somehow fails.
```

Why these Python concepts were used

- ****kwargs** — Accepts arbitrary keyword arguments. Usually for forwarding to another function (a thin wrapper) or to support optional named parameters without listing them all in the signature.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def _gzip_post(url, payload, timeout=120, **kwargs):
    """
    POST JSON payload compressed with gzip.
    Sends Content-Encoding: gzip so the server can decompress it.
    Falls back to normal JSON POST if compression somehow fails.
    """
    try:
        raw = json.dumps(payload).encode('utf-8')
        compressed = _gzip.compress(raw, compresslevel=6)
        headers = kwargs.pop('headers', {})
        headers['Content-Type'] = 'application/json'
        headers['Content-Encoding'] = 'gzip'
        return requests.post(url, data=compressed, headers=headers, timeout=timeout, **kwargs)
    except Exception:
        # Fallback: plain JSON
        return requests.post(url, json=payload, headers={'Content-Type': 'application/json'}, timeout=timeout, **kwargs)
```

```
def _to_topstepx_symbol(sym)
```

Convert Tradovate-style futures symbol to TopStepX-style. Tradovate uses a single-digit year (e.g. NQM6 = NQ June 2026). TopStepX expects a two-digit year (e.g. NQM26). Recognized month codes: F G H J K M N Q U V X Z Returns the input unchanged if it doesn't look like a futures symbol.

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **if** not sym: branches conditionally.
2. Assigns `s = str(sym).strip().upper()`.
3. Assigns `m = re.match('^[A-Z]+([FGHJKMNQUVXZ])(\d{1,2})$', s)`.
4. **if** not m: branches conditionally.
5. Assigns `(root, month, year) = (m.group(1), m.group(2), m.group(3))`.
6. **if** len(year) == 2: branches conditionally.
7. Lazy import from datetime.
8. Assigns `cur_year = _dt.now().year`.
9. Assigns `decade = cur_year // 10 * 10`.
10. Assigns `candidate = decade + int(year)`.
11. **if** candidate < cur_year - 1: branches conditionally.
12. **return** `f'{root}{month}{str(candidate % 100).zfill(2)}'`.

Code (copy-paste safe)

```
def _to_topstepx_symbol(sym):
    """Convert Tradovate-style futures symbol to TopStepX-style.

    Tradovate uses a single-digit year (e.g. NQM6 = NQ June 2026).
    TopStepX expects a two-digit year (e.g. NQM26).

    Recognized month codes: F G H J K M N Q U V X Z
    Returns the input unchanged if it doesn't look like a futures symbol.
    """
    if not sym:
        return sym
    s = str(sym).strip().upper()
    m = re.match(r'^([A-Z]+)([FGHJKMNQUVXZ])(\d{1,2})$', s)
    if not m:
        return s
    root, month, year = m.group(1), m.group(2), m.group(3)
    if len(year) == 2:
        return s # Already in TSX format
    # Expand single-digit year using current decade, rolling forward if needed
    from datetime import datetime as _dt
    cur_year = _dt.now().year
    decade = (cur_year // 10) * 10
    candidate = decade + int(year)
```

```

if candidate < cur_year - 1:
    candidate += 10
return f"{root}{month}{str(candidate % 100).zfill(2)}"

```

```
def main()
```

Main entry point.

Step by step (top-level body)

1. if GUI_AVAILABLE: branches conditionally (with an **else/elif** arm).

Code (copy-paste safe)

```

def main():
    """Main entry point."""
    if GUI_AVAILABLE:
        app = TradeOpssAIApp()
        app.run()
    else:
        print("=" * 50)
        print("Tradeopss AI - Console Mode")
        print("=" * 50)
        print("\nGUI not available. Install tkinter to use the graphical interface.")
        print("\nUsage:")
        print("  1. Set your API key in the dashboard")
        print("  2. Use the MT5DataPusher class programmatically")
        print("\nExample:")
        print("  pusher = MT5DataPusher('http://localhost:5001', 'your-api-key')")
        print("  pusher.connect_mt5(login, password, server)")
        print("  pusher.push_to_dashboard('ClientName', 'AdminName', 'TraderName')")

```

Checkpoint — what works now. Run `python trader_companion/trader_app.py` and the Tkinter window opens — broker selection on first launch, then the main tabbed view that exposes everything you have built in phases 3 through 7.

Chapter 11 — Phase 9 — Web dashboard

A Flask application that admins, managers, and traders log into through a browser. We build the supporting services bottom-up — email, notes, API keys, sheet synchronisation, payout calculations — and finally the Flask app factory in `app.py` that registers the routes and starts the request lifecycle.

Files we build in this phase, in order:

- `dashboard/email_service.py`
- `dashboard/notes_service.py`
- `dashboard/manage_api_keys.py`
- `dashboard/api_client.py`
- `dashboard/utils/sheet_helper.py`
- `dashboard/utils/trade_matcher.py`
- `dashboard/calc_like_sheet.py`
- `dashboard/phase_manager.py`
- `dashboard/watermark_service.py`
- `dashboard/financial_overview.py`
- `dashboard/scheduler.py`
- `dashboard/app.py`

Python concepts you'll meet in this phase

- f-strings (12) · Exceptions (11) · Comprehensions (7) · Context managers (with-statements) (6) · Lambdas (6) · Classes and objects (5) · Type hints (4) · Dunder methods (3)

Each is explained in Chapter 2 (the primer). The number in parentheses is how many of this phase's files use that concept.

Step 11.1 — Build `dashboard/email_service.py`

What to do. Create the file `dashboard/email_service.py` in your project root and paste in the code shown in this step. The file is **260** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

What this file is for. SMTP-backed transactional email helpers — password resets, payout notifications, alert digests.

`dashboard/email_service.py`

260 loc · 0 classes · 4 functions · 5 imports

SMTP-backed transactional email helpers — password resets, payout notifications, alert digests. It defines **4** module-level functions, across **260** lines. Module docstring: *Email Service Module for Trading Dashboard*

Module docstring

Email Service Module for Trading Dashboard Sends email notifications for password changes, account creation, etc.

Python concepts demonstrated in this module

• Context managers (with-statements) • Exceptions • f-strings • Type hints

Imports — what each one is for

```
import smtplib
```

Why imported. SMTP client — sending email. Pairs with the email package, which builds the MIME message.

Used in this file. smtplib.SMTP

Example. `smtplib.send_message(msg)` # where msg is an EmailMessage

Other common scenarios.

- `SMTP_SSL(host, 465)` for implicit-TLS providers
- `starttls()` upgrades a plain connection to TLS
- `login(user, password)` authenticates

```
import os
```

Why imported. Operating-system interface. Path manipulation, environment variables, working-directory operations, exit codes, and thin wrappers around POSIX/Windows syscalls.

Used in this file. `os.getenv`

Example. `os.path.join(root, 'subdir', 'file.txt')` # joins with the OS-correct separator

Other common scenarios.

- `os.environ.get('API_KEY')` to read environment variables
- `os.makedirs(path, exist_ok=True)` to create nested directories
- `os.listdir(path)` to list a directory's contents
- `os.remove(path)` / `os.rename(src, dst)` to delete or move a file
- `os.getcwd()` / `os.chdir(path)` to inspect or change the working dir

```
from email.mime.text import MIMEText
```

Why imported. Build and parse email messages — headers, MIME parts, attachments. Pairs with `smtplib` for sending.

Used in this file. MIMEText

Example. `msg = EmailMessage(); msg['To'] = 'a@b.com'; msg.set_content('hi')`

Other common scenarios.

- `msg.add_attachment(data, maintype='application', subtype='pdf')`
- `email.utils.formataddr(('Name', 'a@b.com'))` builds an addr

`from email.mime.multipart import MIMEMultipart`

Why imported. Build and parse email messages — headers, MIME parts, attachments. Pairs with `smtpplib` for sending.

Used in this file. MIMEMultipart

Example. `msg = EmailMessage(); msg['To'] = 'a@b.com'; msg.set_content('hi')`

Other common scenarios.

- `msg.add_attachment(data, maintype='application', subtype='pdf')`
- `email.utils.formataddr(('Name', 'a@b.com'))` builds an addr

`from datetime import datetime`

Why imported. Dates, times, durations. The fundamental temporal types: `date`, `time`, `datetime`, `timedelta`, `timezone`.

Used in this file. `datetime`

Example. `datetime.now() - timedelta(days=7)` # one week ago

Other common scenarios.

- `datetime.strptime(s, '%Y-%m-%d')` parses a string
- `datetime.strftime(fmt)` formats one
- `datetime.fromtimestamp(n)` converts a Unix epoch
- `datetime.utcnow()` for UTC (better: `datetime.now(timezone.utc)`)

Module constants

Each line below is followed by a plain-English note explaining what it does and why it is written that way.

`SMTP_SERVER = os.getenv('SMTP_SERVER', 'smtp.gmail.com')`

Reads `SMTP_SERVER` from the environment, defaulting to `'smtp.gmail.com'` when not set — overridable per environment without a code change.

`SMTP_PORT = int(os.getenv('SMTP_PORT', '587'))`

Reads `SMTP_PORT` from the environment and converts it to `int` (env vars are always strings). Falls back to `'587'` when unset.

`SMTP_USERNAME = os.getenv('SMTP_USERNAME', '')`

Reads `SMTP_USERNAME` from the environment, defaulting to `"` when not set — overridable per environment without a code change.

```
SMTP_PASSWORD = os.getenv('SMTP_PASSWORD', '')
```

Reads SMTP_PASSWORD from the environment, defaulting to "" when not set — overridable per environment without a code change.

```
FROM_EMAIL = os.getenv('FROM_EMAIL', SMTP_USERNAME)
```

Reads FROM_EMAIL from the environment, defaulting to SMTP_USERNAME when not set — overridable per environment without a code change.

```
FROM_NAME = os.getenv('FROM_NAME', 'Trading Dashboard')
```

Reads FROM_NAME from the environment, defaulting to 'Trading Dashboard' when not set — overridable per environment without a code change.

```
EMAIL_ENABLED = os.getenv('EMAIL_ENABLED', 'false').lower() == 'true'
```

Boolean feature flag. Reads EMAIL_ENABLED from the environment, lowercases it, and compares to 'true' — producing a real Python bool. Defaults to 'false'.

Functions

```
def send_email(to_email: str, subject: str, html_body: str, text_body: str=None) -> bool
```

Send an email using SMTP. Returns True if successful, False otherwise.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., to_email: str, subject: str, html_body: str). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type -> bool. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **if** not EMAIL_ENABLED: branches conditionally.
2. **if** not SMTP_USERNAME or not SMTP_PASSWORD: branches conditionally.
3. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def send_email(to_email: str, subject: str, html_body: str, text_body: str = None) -> bool:
    """
    Send an email using SMTP.
```

```

Returns True if successful, False otherwise.

```

```
def send_password_changed_notification(to_email: str, username: str, changed_by: str='self') -> bool
```

Send notification when password is changed.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `to_email: str`, `username: str`, `changed_by: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> bool`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `timestamp = datetime.now().strftime('%B %d, %Y at %l:%M %p')`.
2. **if** `changed_by == 'self'`: branches conditionally (with an **else/elif** arm).

3. Assigns text_body = f'Hi {username}, your password was changed on {timestamp}....

4. return send_email(to_email, subject, html_body, text_body).

Code (copy-paste safe)

```
def send_password_changed_notification(to_email: str, username: str, changed_by: str = 'self') -> bool:
    """Send notification when password is changed."""
    timestamp = datetime.now().strftime("%B %d, %Y at %I:%M %p")

    if changed_by == 'self':
        subject = "Password Changed Successfully - Trading Dashboard"
        html_body = f"""

```

```

def send_account_created_notification(to_email: str, username: str, temp_password: str,
    user_type: str) -> bool

```

Send notification when a new account is created.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `to_email: str`, `username: str`, `temp_password: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> bool`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `subject = 'Welcome to Trading Dashboard - Your Account is Ready'.`
2. Assigns `role_display = {'admin': 'Administrator', 'trader': 'Trader', 'client': ...}`
3. Assigns `html_body = f"""<!DOCTYPE html>\n <html>\n <head>\n ...`
4. Assigns `text_body = f'Welcome {username}! Your {role_display} account is read....`

5. **return** send_email(to_email, subject, html_body, text_body).

Code (copy-paste safe)

```
def send_account_created_notification(to_email: str, username: str, temp_password: str,
    user_type: str) -> bool:
    """Send notification when a new account is created."""
    subject = "Welcome to Trading Dashboard - Your Account is Ready"

    role_display = {
        'admin': 'Administrator',
        'trader': 'Trader',
        'client': 'Client'
    }.get(user_type, user_type.title())

return send_email(to_email, subject, html_body, text_body)

```

```
def send_password_reset_with_temp(to_email: str, username: str, temp_password: str) -> bool
```

Send email with temporary password after admin reset.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `to_email: str`, `username: str`, `temp_password: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> bool`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `subject = 'Your Password Has Been Reset - Trading Dashboard'`.
2. Assigns `timestamp = datetime.now().strftime('%B %d, %Y at %I:%M %p')`.
3. Assigns `html_body = f"""\n <!DOCTYPE html>\n <html>\n <head>\n ....`
4. Assigns `text_body = f'Hi {username}, your password was reset on {timestamp}'. ....`
5. **return** `send_email(to_email, subject, html_body, text_body)`.

Code (copy-paste safe)

```

def send_password_reset_with_temp(to_email: str, username: str, temp_password: str) -> bool:
    """Send email with temporary password after admin reset."""
    subject = "Your Password Has Been Reset - Trading Dashboard"
    timestamp = datetime.now().strftime("%B %d, %Y at %I:%M %p")

    html_body = f"""
    <!DOCTYPE html>
    <html>
    <head>
        <style>
            body {{ font-family: -apple-system, BlinkMacSystemFont, 'Segoe UI', Roboto, sans-serif; }}
            .container {{ max-width: 600px; margin: 0 auto; padding: 20px; }}
            .header {{ background: linear-gradient(135deg,
                #f59e0b 0%, #d97706 100%); color: white; padding: 30px; text-align: center; border-radius:
            .content {{ background: #f8f9fa; padding: 30px; border-radius: 0 0 10px 10px; }}
            .credentials {{
                background: white; padding: 20px; border-radius: 8px; border: 2px solid #f59e0b; margin:

"""

text_body = f"Hi {username}, your password was reset on {timestamp}. Temporary password: {temp_password}"

return send_email(to_email, subject, html_body, text_body)

```

Step 11.2 — Build dashboard/notes_service.py

What to do. Create the file `dashboard/notes_service.py` in your project root and paste in the code shown in this step. The file is **76** lines long; we walk through it piece by piece below.

Depends on. This file imports from internal modules built in earlier steps: `dashboard`. If any of those imports fail, jump back to the step that introduced them.

What this file is for. Per-account notes (free-text annotations admins leave on trader accounts).

dashboard/notes_service.py

76 loc · 0 classes · 3 functions · 2 imports

Per-account notes (free-text annotations admins leave on trader accounts). It defines **3** module-level functions, across **76** lines.

Python concepts demonstrated in this module

- Context managers (with-statements)
- Exceptions
- f-strings

Imports — what each one is for

```
from dashboard.database import get_connection
```

Why imported. Internal package — the Flask dashboard. See chapter on dashboard/.

Used in this file. `get_connection`

```
import logging
```

Why imported. Structured, levelled logging. Replaces `print()` with filterable, formattable output that can route to files, stderr, syslog, or HTTP endpoints.

Used in this file. `logging.error`

Example. `logging.getLogger(__name__).info('connected to %s', host)`

Other common scenarios.

- `.debug()` / `.info()` / `.warning()` / `.error()` / `.exception()`
- `logger.exception()` captures the current traceback automatically
- `logging.basicConfig(level=logging.INFO)` for quick setup
- Handlers and Formatters route logs to files / streams / syslog

Functions

```
def get_client_notes(client_id)
```

Returns a dictionary of notes for a client. Format: { row_index: { column_key: note_content } }

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def get_client_notes(client_id):
    """
    Returns a dictionary of notes for a client.
    Format: { row_index: { column_key: note_content } }
    """
    try:
        with get_connection() as conn:
            cursor = conn.cursor()
            cursor.execute(''
                SELECT row_index, column_key, note_content
                FROM cell_notes
```

```

        WHERE client_id = ?
''' , (client_id,))
rows = cursor.fetchall()

notes = {}
for row in rows:
    # Handle both dict-like (Row) and tuple results
    try:
        rid = row['row_index']
        col = row['column_key']
        content = row['note_content']
    except (TypeError, IndexError):
        rid = row[0]
        col = row[1]
        content = row[2]

    if rid not in notes:
        notes[rid] = {}
    notes[rid][col] = content
return notes
except Exception as e:
    logging.error(f"Error fetching notes for {client_id}: {e}")
return {}

```

```
def save_client_note(client_id, row_index, column_key, content, user)
```

Saves or updates a note.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

def save_client_note(client_id, row_index, column_key, content, user):
    """
    Saves or updates a note.
    """
    try:
        with get_connection() as conn:
            cursor = conn.cursor()
            cursor.execute('''
                INSERT INTO cell_notes (client_id, row_index, column_key, note_content, created_by,
                    updated_at)
                VALUES (?, ?, ?, ?, ?, CURRENT_TIMESTAMP)
                ON CONFLICT (client_id, row_index, column_key) DO UPDATE
                SET note_content = EXCLUDED.note_content,
                    created_by = EXCLUDED.created_by,

```

```

        updated_at = CURRENT_TIMESTAMP
        '''', (client_id, row_index, column_key, content, user))
    conn.commit()
    return True
except Exception as e:
    logging.error(f"Error saving note for {client_id}: {e}")
    return False

```

```
def delete_client_note(client_id, row_index, column_key)
```

Deletes a specific note.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

def delete_client_note(client_id, row_index, column_key):
    """
    Deletes a specific note.
    """
    try:
        with get_connection() as conn:
            cursor = conn.cursor()
            cursor.execute(''
                DELETE FROM cell_notes
                WHERE client_id = ? AND row_index = ? AND column_key = ?
            ''', (client_id, row_index, column_key))
            conn.commit()
            return True
    except Exception as e:
        logging.error(f"Error deleting note for {client_id}: {e}")
        return False

```

Step 11.3 — Build dashboard/manage_api_keys.py

What to do. Create the file `dashboard/manage_api_keys.py` in your project root and paste in the code shown in this step. The file is **231** lines long; we walk through it piece by piece below.

Depends on. This file imports from internal modules built in earlier steps: `dashboard`. If any of those imports fail, jump back to the step that introduced them.

What this file is for. Creates and revokes API keys used by the desktop companion to authenticate to the dashboard's ingestion endpoints.

dashboard/manage_api_keys.py

231 loc · 0 classes · 9 functions · 3 imports

Creates and revokes API keys used by the desktop companion to authenticate to the dashboard's ingestion endpoints. It defines **9** module-level functions, across **231** lines. Module docstring: *Secure API Key Management Tool*

Module docstring

Secure API Key Management Tool Manages API keys stored with SHA-256 hashing in SQLite database

Python concepts demonstrated in this module

- f-strings

Imports — what each one is for

```
import os
```

Why imported. Operating-system interface. Path manipulation, environment variables, working-directory operations, exit codes, and thin wrappers around POSIX/Windows syscalls.

Used in this file. `os.path`, `os.path.abspath`, `os.path.dirname`

Example. `os.path.join(root, 'subdir', 'file.txt')` # joins with the OS-correct separator

Other common scenarios.

- `os.environ.get('API_KEY')` to read environment variables
- `os.makedirs(path, exist_ok=True)` to create nested directories
- `os.listdir(path)` to list a directory's contents
- `os.remove(path)` / `os.rename(src, dst)` to delete or move a file
- `os.getcwd()` / `os.chdir(path)` to inspect or change the working dir

```
import sys
```

Why imported. Access to the running interpreter — `argv`, `stdin/stdout`, exit codes, the import search path, and the platform name.

Used in this file. `sys.path`, `sys.path.insert`

Example. `sys.exit(1)` # terminate the process with a non-zero status

Other common scenarios.

- `sys.argv[1:]` reads the command-line arguments
- `sys.path.insert(0, 'extra')` prepends to the import search path
- `sys.stderr.write(msg)` writes to standard error
- `sys.platform` tells you 'win32', 'linux', or 'darwin'
- `sys.modules` is the global cache of already-imported modules

```
from dashboard.database import generate_api_key
from dashboard.database import list_api_keys
from dashboard.database import revoke_api_key
from dashboard.database import delete_api_key
from dashboard.database import verify_admin_password
from dashboard.database import set_admin_password
from dashboard.database import get_audit_log
```

Why imported. Internal package — the Flask dashboard. See chapter on dashboard/.

Used in this file. `delete_api_key`, `generate_api_key`, `get_audit_log`, `list_api_keys`, `revoke_api_key`, `set_admin_password`, `verify_admin_password`

Functions

```
def print_header()
```

Step by step (top-level body)

1. Calls `print(...)` for its side effect.
2. Calls `print(...)` for its side effect.
3. Calls `print(...)` for its side effect.
4. Calls `print(...)` for its side effect.

Code (copy-paste safe)

```
def print_header():
    print("\n" + "=" * 60)
    print("    SECURE API KEY MANAGEMENT")
    print("    (Keys are hashed - never stored in plain text)")
    print("=" * 60)
```

```
def authenticate()
```

Require admin password to access management functions.

Step by step (top-level body)

1. Calls `print(...)` for its side effect.
2. Assigns `password = input('Enter admin password: ').strip()`.
3. `if not verify_admin_password('super_admin', password):` branches conditionally.
4. Calls `print(...)` for its side effect.
5. `return True`.

Code (copy-paste safe)

```
def authenticate():
    """Require admin password to access management functions."""
    print("\nAdmin authentication required.")
    password = input("Enter admin password: ").strip()

    if not verify_admin_password('super_admin', password):
        print("■ Invalid password!")
        return False

    print("✓ Authentication successful\n")
    return True
```

```
def list_keys()
```

Display all API keys (showing prefix only).

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns keys = list_api_keys().
2. Calls print(...) for its side effect.
3. Calls print(...) for its side effect.
4. Calls print(...) for its side effect.
5. if not keys: branches conditionally.
6. Calls print(...) for its side effect.
7. Calls print(...) for its side effect.
8. for key in keys: iterates.
9. Calls print(...) for its side effect.
10. Calls print(...) for its side effect.

Code (copy-paste safe)

```
def list_keys():
    """Display all API keys (showing prefix only)."""
    keys = list_api_keys()

    print("\n" + "=" * 60)
    print("API KEYS (Prefix Only - Full keys are never stored)")
    print("=" * 60)

    if not keys:
        print("No API keys found.")
        return

    print(f"{'Prefix':<15} {'Trader':<15} {'Admin':<15} {'Active':<8} {'Last Used'}")
```

```

print("-" * 75)

for key in keys:
    active = "✓" if key['is_active'] else "✗"
    last_used = key['last_used'] or "Never"
    if len(last_used) > 19:
        last_used = last_used[:19]
    print(f"{key['key_prefix']:<15} {key['trader']:<15} {key['admin']:<15} {active:<8} {last_used}")

print("-" * 75)
print(f"Total: {len(keys)} keys")

```

```
def generate_new_key()
```

Generate a new API key for a trader.

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Calls `print(...)` for its side effect.
2. Assigns `trader = input('Trader name: ').strip()`.
3. **if not trader**: branches conditionally.
4. Assigns `admin = input('Admin name (default: same as trader): ').strip()` or...
5. Assigns `client = input('Client name (optional): ').strip()`.
6. Calls `print(...)` for its side effect.
7. Assigns `api_key = generate_api_key(admin, trader, client)`.
8. **if api_key**: branches conditionally (with an **else/elif** arm).

Code (copy-paste safe)

```

def generate_new_key():
    """Generate a new API key for a trader."""
    print("\n--- Generate New API Key ---")

    trader = input("Trader name: ").strip()
    if not trader:
        print("■ Trader name required!")
        return

    admin = input("Admin name (default: same as trader): ").strip() or trader
    client = input("Client name (optional): ").strip()

    print("\nGenerating API key...")
    api_key = generate_api_key(admin, trader, client)

    if api_key:
        print("\n" + "=" * 60)
        print("✓ API KEY GENERATED SUCCESSFULLY")
        print("=" * 60)
        print(f"\nTrader: {trader}")
        print(f"Admin: {admin}")

```

```

if client:
    print(f"Client: {client}")
    print(f"\n■ API KEY: {api_key}")
    print("\n■■■ IMPORTANT: Save this key now!")
    print("    It will NEVER be shown again.")
    print("    The key is stored as a hash and cannot be recovered.")
    print("=" * 60)
else:
    print("■ Failed to generate API key!")

```

```
def revoke_key()
```

Revoke an existing API key.

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Calls `print(...)` for its side effect.
2. Calls `list_keys(...)` for its side effect.
3. Assigns `key_prefix = input('\nEnter key prefix to revoke (e.g., tk_abc123...):....`
4. **if not** `key_prefix`: branches conditionally.
5. Assigns `confirm = input(f'Are you sure you want to revoke key '{key_prefix}....`
6. **if** `confirm != 'yes'`: branches conditionally.
7. **if** `revoke_api_key(key_prefix)`: branches conditionally (with an **else/elif** arm).

Code (copy-paste safe)

```

def revoke_key():
    """Revoke an existing API key."""
    print("\n--- Revoke API Key ---")

    # Show current keys first
    list_keys()

    key_prefix = input("\nEnter key prefix to revoke (e.g., tk_abc123...): ").strip()
    if not key_prefix:
        print("■ Key prefix required!")
        return

    confirm = input(f"Are you sure you want to revoke key '{key_prefix}'? (yes/no): ").strip().lower()
    if confirm != 'yes':
        print("Cancelled.")
        return

    if revoke_api_key(key_prefix):
        print(f"✓ API key '{key_prefix}' has been revoked!")
    else:
        print(f"■ API key '{key_prefix}' not found!")

def permanently_delete_key()

```

Permanently delete an API key.

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Calls `print(...)` for its side effect.
2. Calls `list_keys(...)` for its side effect.
3. Assigns `key_prefix = input('\nEnter key prefix to DELETE (e.g., tk_abc123...):....`
4. **if** `not key_prefix`: branches conditionally.
5. Calls `print(...)` for its side effect.
6. Assigns `confirm = input(f"Type 'DELETE' to permanently remove key '{key_pre....`
7. **if** `confirm != 'DELETE'`: branches conditionally.
8. **if** `delete_api_key(key_prefix)`: branches conditionally (with an **else/elif** arm).

Code (copy-paste safe)

```
def permanently_delete_key():
    """Permanently delete an API key."""
    print("\n--- Permanently Delete API Key ---")

    # Show current keys first
    list_keys()

    key_prefix = input("\nEnter key prefix to DELETE (e.g., tk_abc123...): ").strip()
    if not key_prefix:
        print("■ Key prefix required!")
        return

    print("\n■■■ WARNING: This action cannot be undone!")
    confirm = input(f"Type 'DELETE' to permanently remove key '{key_prefix}': ").strip()
    if confirm != 'DELETE':
        print("Cancelled.")
        return

    if delete_api_key(key_prefix):
        print(f"✓ API key '{key_prefix}' has been permanently deleted!")
    else:
        print(f"■ API key '{key_prefix}' not found!")

def view_audit_log()
```

View recent audit log entries.

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Calls `print(...)` for its side effect.
2. Assigns `limit = input('Number of entries to show (default: 20): ').strip()`.
3. Assigns `limit = int(limit)` if `limit.isdigit()` else 20.
4. Assigns `action_filter = input('Filter by action (leave empty for all): ').strip()....`
5. Assigns `logs = get_audit_log(limit, action_filter)`.
6. Calls `print(...)` for its side effect.
7. Calls `print(...)` for its side effect.
8. Calls `print(...)` for its side effect.
9. `if not logs`: branches conditionally.
10. `for log in logs`: iterates.
11. Calls `print(...)` for its side effect.
12. Calls `print(...)` for its side effect.

Code (copy-paste safe)

```
def view_audit_log():
    """View recent audit log entries."""
    print("\n--- Audit Log ---")

    limit = input("Number of entries to show (default: 20): ").strip()
    limit = int(limit) if limit.isdigit() else 20

    action_filter = input("Filter by action (leave empty for all): ").strip() or None

    logs = get_audit_log(limit, action_filter)

    print("\n" + "=" * 80)
    print("AUDIT LOG")
    print("=" * 80)

    if not logs:
        print("No log entries found.")
        return

    for log in logs:
        timestamp = log['timestamp'][:19] if len(log['timestamp']) > 19 else log['timestamp']
        success = "✓" if log['success'] else "✗"
        print(f"[{timestamp}] {success} {log['action'][:25]} | {log['user_type']}: {log['user_identifier']}")
        if log['details']:
            print(f"    ■■■ {log['details']}")

    print("-" * 80)
    print(f"Showing {len(logs)} entries")

def change_admin_password()
    Change the admin password.
```

Step by step (top-level body)

1. Calls `print(...)` for its side effect.
2. Assigns `current = input('Enter current password: ').strip()`.
3. **if** `not verify_admin_password('super_admin', current)`: branches conditionally.
4. Assigns `new_password = input('Enter new password (min 8 characters): ').strip()`.
5. **if** `len(new_password) < 8`: branches conditionally.
6. Assigns `confirm = input('Confirm new password: ').strip()`.
7. **if** `new_password != confirm`: branches conditionally.
8. **if** `set_admin_password('super_admin', new_password)`: branches conditionally (with an **else/elif** arm).

Code (copy-paste safe)

```
def change_admin_password():
    """Change the admin password."""
    print("\n--- Change Admin Password ---")

    current = input("Enter current password: ").strip()
    if not verify_admin_password('super_admin', current):
        print("■ Invalid current password!")
        return

    new_password = input("Enter new password (min 8 characters): ").strip()
    if len(new_password) < 8:
        print("■ Password must be at least 8 characters!")
        return

    confirm = input("Confirm new password: ").strip()
    if new_password != confirm:
        print("■ Passwords don't match!")
        return

    if set_admin_password('super_admin', new_password):
        print("✓ Password changed successfully!")
    else:
        print("■ Failed to change password!")

def main()
```

Step by step (top-level body)

1. Calls `print_header(...)` for its side effect.
2. **if** `not authenticate()`: branches conditionally.
3. **while** `True`: loops until the condition is false.

Code (copy-paste safe)

```
def main():
    print_header()

    # Authenticate first
    if not authenticate():
        return
```

```

while True:
    print("\n" + "-" * 40)
    print("OPTIONS:")
    print("1. Generate new API key")
    print("2. List all API keys")
    print("3. Revoke API key")
    print("4. Permanently delete API key")
    print("5. View audit log")
    print("6. Change admin password")
    print("7. Exit")
    print("-" * 40)

    choice = input("\nSelect option (1-7): ").strip()

    if choice == '1':
        generate_new_key()
    elif choice == '2':
        list_keys()
    elif choice == '3':
        revoke_key()
    elif choice == '4':
        permanently_delete_key()
    elif choice == '5':
        view_audit_log()
    elif choice == '6':
        change_admin_password()
    elif choice == '7':
        print("\nGoodbye!")
        break
    else:
        print("Invalid option. Please select 1-7.")

```

Step 11.4 — Build dashboard/api_client.py

What to do. Create the file `dashboard/api_client.py` in your project root and paste in the code shown in this step. The file is **201** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

What this file is for. Outbound HTTP client used by the dashboard to talk to external APIs (Google Sheets, prop-firm endpoints).

dashboard/api_client.py

201 loc · 1 classes · 0 functions · 4 imports

Outbound HTTP client used by the dashboard to talk to external APIs (Google Sheets, prop-firm endpoints). It defines **1** class, across **201** lines. Module docstring: *Dashboard API Client for MT5 Traders*

Module docstring

Dashboard API Client for MT5 Traders This module allows traders to send data from their local MT5 software to the hosted dashboard.

Python concepts demonstrated in this module

• Classes and objects • Dunder methods • Exceptions • f-strings • Type hints

Imports — what each one is for

```
import requests
```

Why imported. The de-facto Python HTTP client. Synchronous; trades raw speed for an extremely friendly API.

Used in this file. `requests.exceptions`, `requests.exceptions.RequestException`, `requests.get`, `requests.post`

Example. `requests.get(url, timeout=10).json()`

Other common scenarios.

- `Session()` reuses TCP connections across calls
- `params=`, `headers=`, `json=`, `data=` for query/body shapes
- `raise_for_status()` turns 4xx/5xx into an exception
- `stream=True` for large downloads

```
import json
```

Why imported. JSON encoding and decoding — the standard wire format for config files, API payloads, and inter-process messages.

Used in this file. *No direct attribute access detected — likely imported for side effects, re-export, or string references.*

Example. `json.loads(response.text)` # parse a JSON string to dict

Other common scenarios.

- `json.dumps(obj, indent=2)` for pretty-printing
- `json.dump(obj, file)` / `json.load(file)` for file I/O
- `default=str` handles non-serialisable types like `datetime`
- `object_hook=` customises decoding (e.g., to `dataclass` instances)

```
from datetime import datetime
```

Why imported. Dates, times, durations. The fundamental temporal types: `date`, `time`, `datetime`, `timedelta`, `timezone`.

Used in this file. *No direct attribute access detected — likely imported for side effects, re-export, or string references.*

Example. `datetime.now() - timedelta(days=7)` # one week ago

Other common scenarios.

- `datetime.strptime(s, '%Y-%m-%d')` parses a string
- `datetime.strftime(fmt)` formats one
- `datetime.fromtimestamp(n)` converts a Unix epoch
- `datetime.utcnow()` for UTC (better: `datetime.now(timezone.utc)`)

```
from typing import Dict
from typing import List
from typing import Optional
```

Why imported. Type-hint primitives — generics, unions, Optional, Callable, Protocol, TypeVar, TypedDict.

Used in this file. List, Optional

Example. `def lookup(k: str) -> Optional[int]: ...`

Other common scenarios.

- `List[int]` / `Dict[str, Any]` / `Tuple[int, str]` (or bare `list[int]`+ on 3.9+)
- `Callable[[int, int], int]` for function signatures
- Protocol for structural typing (duck typing with checks)
- `TypeVar('T')` for generic functions and classes

Classes

```
class DashboardAPIClient
```

Client to communicate with the hosted dashboard API.

Code (copy-paste safe)

```
class DashboardAPIClient:
    """Client to communicate with the hosted dashboard API."""

    def __init__(self, api_url: str, api_key: str, client_id: Optional[str] = None):
        """
        Initialize the Dashboard API client.

        Args:
            api_url: Base URL of the dashboard API (e.g., 'https://yourusername.pythonanywhere.com')
            api_key: API key for authentication
            client_id: Optional client ID (if not set in API key)
        """
        self.api_url = api_url.rstrip('/')
        self.api_key = api_key
        self.client_id = client_id
        self.headers = {
            'Content-Type': 'application/json',
            'X-API-Key': self.api_key
        }

    def _post(self, endpoint: str, data: dict) -> dict:
        """Make a POST request to the API."""
        try:
            response = requests.post(
                f"{self.api_url}{endpoint}",
```

```

        headers=self.headers,
        json=data,
        timeout=10
    )
    response.raise_for_status()
    return response.json()
except requests.exceptions.RequestException as e:
    print(f"API Error: {e}")
    return {"status": "error", "message": str(e)}

    """Make a GET request to the API."""
    try:
        response = requests.get(
            f"{self.api_url}{endpoint}",
            headers=self.headers,
            timeout=10
        )
        response.raise_for_status()
        return response.json()
    except requests.exceptions.RequestException as e:
        print(f"API Error: {e}")
        return {"status": "error", "message": str(e)}

def push_account_data(self, account: dict, client_id: Optional[str] = None) -> dict:
    """
    Push account information to the dashboard.

    Args:
        account: Dictionary containing account info (balance, equity, margin, etc.)
        client_id: Optional client ID override

    Returns:
        API response dictionary
    """
    data = {
        "account": account,
        "client_id": client_id or self.client_id
    }
    return self._post("/api/trader/push_account", data)

def push_positions(self, positions: List[dict], client_id: Optional[str] = None) -> dict:
    """
    Push current positions to the dashboard.

    Args:
        positions: List of position dictionaries
        client_id: Optional client ID override

    Returns:
        API response dictionary
    """
    data = {
        "positions": positions,
        "client_id": client_id or self.client_id
    }
    return self._post("/api/trader/push_positions", data)

def push_deals(self, deals: List[dict], client_id: Optional[str] = None) -> dict:
    """

```

```

    Push deal history to the dashboard.

    Args:
        deals: List of deal dictionaries
        client_id: Optional client ID override

    Returns:
        API response dictionary
    """
    data = {
        "deals": deals,
        "client_id": client_id or self.client_id
    }
    return self._post("/api/trader/push_deals", data)

def push_evaluations(self, evaluations: List[dict], client_id: Optional[str] = None) -> dict:
    """
    Push evaluation data to the dashboard.

    Args:
        evaluations: List of evaluation dictionaries
        client_id: Optional client ID override

    Returns:
        API response dictionary
    """
    data = {
        "evaluations": evaluations,
        "client_id": client_id or self.client_id
    }
    return self._post("/api/trader/push_evaluations", data)

def push_all_data(self, data: dict) -> dict:
    """
    Push all data at once (account, positions, deals, evaluations).

    Args:
        data: Dictionary containing all data types with identity info

    Returns:
        API response dictionary
    """
    return self._post("/api/update_data", data)

def health_check(self) -> dict:
    """Check if the dashboard API is accessible."""
    return self._get("/api/health")

def get_client_data(self, client_id: Optional[str] = None) -> dict:
    """
    Retrieve client data from the dashboard.

    Args:
        client_id: Optional client ID override

    Returns:
        Client data dictionary
    """
    cid = client_id or self.client_id
    return self._get(f"/api/data?client_id={cid}")

```

Method: DashboardAPIClient.__init__

```
def __init__(self, api_url: str, api_key: str, client_id: Optional[str]=None)
```

Initialize the Dashboard API client. Args: api_url: Base URL of the dashboard API (e.g., 'https://yourusername.pythonanywhere.com') api_key: API key for authentication client_id: Optional client ID (if not set in API key)

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `api_url: str`, `api_key: str`, `client_id: Optional[str]`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **__init__** — The constructor. Runs after Python has allocated the instance; assigns starting attribute values to `self`.

Step by step (top-level body)

1. Assigns `self.api_url = api_url.rstrip('/')`.
2. Assigns `self.api_key = api_key`.
3. Assigns `self.client_id = client_id`.
4. Assigns `self.headers = {'Content-Type': 'application/json', 'X-API-Key': self.ap...`

Code (copy-paste safe)

```
def __init__(self, api_url: str, api_key: str, client_id: Optional[str] = None):
    """
    Initialize the Dashboard API client.

    Args:
        api_url: Base URL of the dashboard API (e.g., 'https://yourusername.pythonanywhere.com')
        api_key: API key for authentication
        client_id: Optional client ID (if not set in API key)
    """
    self.api_url = api_url.rstrip('/')
    self.api_key = api_key
    self.client_id = client_id
    self.headers = {
        'Content-Type': 'application/json',
        'X-API-Key': self.api_key
    }
```

Method: DashboardAPIClient._post

```
def _post(self, endpoint: str, data: dict) -> dict
```

Make a POST request to the API.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `endpoint: str`, `data: dict`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.

- **return type annotation** — Annotated return type -> dict. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def _post(self, endpoint: str, data: dict) -> dict:
    """Make a POST request to the API."""
    try:
        response = requests.post(
            f"{self.api_url}{endpoint}",
            headers=self.headers,
            json=data,
            timeout=10
        )
        response.raise_for_status()
        return response.json()
    except requests.exceptions.RequestException as e:
        print(f"API Error: {e}")
        return {"status": "error", "message": str(e)}
```

Method: DashboardAPIClient._get

```
def _get(self, endpoint: str) -> dict:
    Make a GET request to the API.
```

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., endpoint: str). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type -> dict. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def _get(self, endpoint: str) -> dict:
```

```

"""Make a GET request to the API."""
try:
    response = requests.get(
        f"{self.api_url}{endpoint}",
        headers=self.headers,
        timeout=10
    )
    response.raise_for_status()
    return response.json()
except requests.exceptions.RequestException as e:
    print(f"API Error: {e}")
    return {"status": "error", "message": str(e)}

```

Method: DashboardAPIClient.push_account_data

```
def push_account_data(self, account: dict, client_id: Optional[str]=None) -> dict
```

Push account information to the dashboard. Args: account: Dictionary containing account info (balance, equity, margin, etc.) client_id: Optional client ID override Returns: API response dictionary

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `account: dict`, `client_id: Optional[str]`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> dict`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. Assigns `data = {'account': account, 'client_id': client_id or self.client_id}`
2. `return self._post('/api/trader/push_account', data).`

Code (copy-paste safe)

```

def push_account_data(self, account: dict, client_id: Optional[str] = None) -> dict:
    """
    Push account information to the dashboard.

    Args:
        account: Dictionary containing account info (balance, equity, margin, etc.)
        client_id: Optional client ID override

    Returns:
        API response dictionary
    """
    data = {
        "account": account,
        "client_id": client_id or self.client_id
    }
    return self._post("/api/trader/push_account", data)

```

Method: DashboardAPIClient.push_positions

```
def push_positions(self, positions: List[dict], client_id: Optional[str]=None) -> dict
```

Push current positions to the dashboard. Args: positions: List of position dictionaries client_id: Optional client ID override Returns: API response dictionary

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., positions: List[dict], client_id: Optional[str]). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type -> dict. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. Assigns data = {'positions': positions, 'client_id': client_id or self.c....
2. return self._post('/api/trader/push_positions', data).

Code (copy-paste safe)

```
def push_positions(self, positions: List[dict], client_id: Optional[str] = None) -> dict:
    """
    Push current positions to the dashboard.

    Args:
        positions: List of position dictionaries
        client_id: Optional client ID override

    Returns:
        API response dictionary
    """
    data = {
        "positions": positions,
        "client_id": client_id or self.client_id
    }
    return self._post("/api/trader/push_positions", data)
```

Method: DashboardAPIClient.push_deals

```
def push_deals(self, deals: List[dict], client_id: Optional[str]=None) -> dict

Push deal history to the dashboard. Args: deals: List of deal dictionaries client_id: Optional client ID
override Returns: API response dictionary
```

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., deals: List[dict], client_id: Optional[str]). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type -> dict. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. Assigns data = {'deals': deals, 'client_id': client_id or self.client_id}.

2. **return** self._post('/api/trader/push_deals', data).

Code (copy-paste safe)

```
def push_deals(self, deals: List[dict], client_id: Optional[str] = None) -> dict:
    """
    Push deal history to the dashboard.

    Args:
        deals: List of deal dictionaries
        client_id: Optional client ID override

    Returns:
        API response dictionary
    """
    data = {
        "deals": deals,
        "client_id": client_id or self.client_id
    }
    return self._post("/api/trader/push_deals", data)
```

Method: DashboardAPIClient.push_evaluations

```
def push_evaluations(self, evaluations: List[dict], client_id: Optional[str]=None) -> dict

    Push evaluation data to the dashboard. Args: evaluations: List of evaluation dictionaries client_id:
    Optional client ID override Returns: API response dictionary
```

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., evaluations: List[dict], client_id: Optional[str]). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type -> dict. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. Assigns data = {'evaluations': evaluations, 'client_id': client_id or se....
2. **return** self._post('/api/trader/push_evaluations', data).

Code (copy-paste safe)

```
def push_evaluations(self, evaluations: List[dict], client_id: Optional[str] = None) -> dict:
    """
    Push evaluation data to the dashboard.

    Args:
        evaluations: List of evaluation dictionaries
        client_id: Optional client ID override

    Returns:
        API response dictionary
    """
    data = {
        "evaluations": evaluations,
        "client_id": client_id or self.client_id
    }
```

```

    }
    return self._post("/api/trader/push_evaluations", data)

```

Method: DashboardAPIClient.push_all_data

```
def push_all_data(self, data: dict) -> dict
```

Push all data at once (account, positions, deals, evaluations). Args: data: Dictionary containing all data types with identity info Returns: API response dictionary

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., data: dict). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type -> dict. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. **return** self._post('/api/update_data', data).

Code (copy-paste safe)

```

def push_all_data(self, data: dict) -> dict:
    """
        Push all data at once (account, positions, deals, evaluations).

        Args:
            data: Dictionary containing all data types with identity info

        Returns:
            API response dictionary
    """
    return self._post("/api/update_data", data)

```

Method: DashboardAPIClient.health_check

```
def health_check(self) -> dict
```

Check if the dashboard API is accessible.

Why these Python concepts were used

- **return type annotation** — Annotated return type -> dict. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. **return** self._get('/api/health').

Code (copy-paste safe)

```

def health_check(self) -> dict:
    """Check if the dashboard API is accessible."""
    return self._get("/api/health")

```

Method: DashboardAPIClient.get_client_data

```
def get_client_data(self, client_id: Optional[str]=None) -> dict
```

Retrieve client data from the dashboard. Args: client_id: Optional client ID override Returns: Client data dictionary

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `client_id: Optional[str]`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> dict`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `cid = client_id` or `self.client_id`.
2. **return** `self._get(f'/api/data?client_id={cid}')`.

Code (copy-paste safe)

```
def get_client_data(self, client_id: Optional[str] = None) -> dict:
    """
    Retrieve client data from the dashboard.

    Args:
        client_id: Optional client ID override

    Returns:
        Client data dictionary
    """
    cid = client_id or self.client_id
    return self._get(f"/api/data?client_id={cid}")
```

Step 11.5 — Build dashboard/utils/sheet_helper.py

What to do. Create the file `dashboard/utils/sheet_helper.py` in your project root and paste in the code shown in this step. The file is **253** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

What this file is for. Thin wrapper over the Google Sheets API.

dashboard/utils/sheet_helper.py

253 loc · 0 classes · 6 functions · 5 imports

Thin wrapper over the Google Sheets API. It defines **6** module-level functions, across **253** lines.

Python concepts demonstrated in this module

• Comprehensions • Exceptions • f-strings • Lambdas

Imports — what each one is for

```
import pandas as pd
```

Why imported. DataFrame library — the workhorse for tabular data: loading CSV/Excel/SQL, joins, aggregations, time-series.

Used in this file. `pd.isna`, `pd.read_csv`, `pd.to_datetime`

Example. `df = pd.read_csv(path); df.groupby('symbol')['pnl'].sum()`

Other common scenarios.

- `df.merge(other, on='key')` joins like SQL
- `df.resample('1D').agg(...)` for time-series rebucketing
- `df.to_sql` / `df.to_excel` / `df.to_parquet` for output
- `df.loc[mask, 'col']` for label-based selection/assignment

```
import requests
```

Why imported. The de-facto Python HTTP client. Synchronous; trades raw speed for an extremely friendly API.

Used in this file. `requests.get`

Example. `requests.get(url, timeout=10).json()`

Other common scenarios.

- `Session()` reuses TCP connections across calls
- `params=`, `headers=`, `json=`, `data=` for query/body shapes
- `raise_for_status()` turns 4xx/5xx into an exception
- `stream=True` for large downloads

```
import io
```

Why imported. In-memory streams and the abstract base classes for file objects. Useful when an API expects a file but you only have bytes/text in memory.

Used in this file. `io.StringIO`

Example. `io.BytesIO(b'data')` # behaves like an open binary file

Other common scenarios.

- `io.StringIO('text')` for an in-memory text stream
- `io.TextIOWrapper` wraps a binary stream with an encoding

```
import logging
```

Why imported. Structured, levelled logging. Replaces print() with filterable, formattable output that can route to files, stderr, syslog, or HTTP endpoints.

Used in this file. logging.debug, logging.error

Example. logging.getLogger(__name__).info('connected to %s', host)

Other common scenarios.

- .debug() / .info() / .warning() / .error() / .exception()
- logger.exception() captures the current traceback automatically
- logging.basicConfig(level=logging.INFO) for quick setup
- Handlers and Formatters route logs to files / streams / syslog

```
from datetime import datetime
```

Why imported. Dates, times, durations. The fundamental temporal types: date, time, datetime, timedelta, timezone.

Used in this file. *No direct attribute access detected — likely imported for side effects, re-export, or string references.*

Example. datetime.now() - timedelta(days=7) # one week ago

Other common scenarios.

- datetime.strptime(s, '%Y-%m-%d') parses a string
- datetime.strftime(fmt) formats one
- datetime.fromtimestamp(n) converts a Unix epoch
- datetime.utcnow() for UTC (better: datetime.now(timezone.utc))

Module constants

Each line below is followed by a plain-English note explaining what it does and why it is written that way.

```
SHEET_ID = '10eGsivGm5G0aH0orB2AAbjpXzDwDkYY1gIZgux9nIjI'
```

String literal — fixed at code-load time.

```
STATS_GID = '839895136'
```

String literal — fixed at code-load time.

```
WATERLOG_GID = '520289647'
```

String literal — fixed at code-load time.

```
WATERLOG_TAB_NAME = 'Profitability Waterlog'
```

String literal — fixed at code-load time.

Functions

```
def get_sheet_csv(gid, sheet_id=None)
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `sid = sheet_id` or `SHEET_ID`.
2. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def get_sheet_csv(gid, sheet_id=None):
    sid = sheet_id or SHEET_ID
    try:
        url = f"https://docs.google.com/spreadsheets/d/{sid}/export?format=csv&gid={gid}"
        response = requests.get(url, timeout=10)
        response.raise_for_status()
        return response.content.decode('utf-8')
    except Exception as e:
        logging.error(f"Error fetching sheet CSV (gid={gid}): {e}")
        return None
```

```
def _extract_sheet_id(sheet_url)
```

Extract the spreadsheet key from a Google Sheets URL.

Why these Python concepts were used

- **ternary expression** — Uses `x` if `cond` else `y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Imports `re` (lazy import inside the function).
2. **if not** `sheet_url`: branches conditionally.
3. Assigns `m = re.search('/spreadsheets/d/([a-zA-Z0-9-_-]+)', sheet_url)`.
4. **return** `m.group(1)` if `m` else `None`.

Code (copy-paste safe)

```
def _extract_sheet_id(sheet_url):
    """Extract the spreadsheet key from a Google Sheets URL."""
    import re
    if not sheet_url:
        return None
    m = re.search(r'/spreadsheets/d/([a-zA-Z0-9-_-]+)', sheet_url)
    return m.group(1) if m else None
```

```
def _discover_waterlog_gid(sheet_id)
```

Try to discover the Profitability Waterlog GID from the sheet's HTML.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Imports `re` (lazy import inside the function).
2. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def _discover_waterlog_gid(sheet_id):
    """Try to discover the Profitability Waterlog GID from the sheet's HTML."""
    import re
    try:
        url = f"https://docs.google.com/spreadsheets/d/{sheet_id}/edit"
        resp = requests.get(url, timeout=10)
        if resp.status_code != 200:
            return None
        content = resp.text
        safe_name = re.escape(WATERLOG_TAB_NAME)
        for m in re.finditer(safe_name, content):
            window = content[max(0, m.start() - 300):m.start()]
            candidates = re.findall(r'\\?"(\\d+)\\?"(?!\\s*:)', window)
            valid = [c for c in candidates if len(c) > 5]
            if valid:
                return valid[-1]
        return None
    except Exception as e:
        logging.error(f"Error discovering waterlog GID: {e}")
        return None
```

```
def fetch_waterlog_data(sheet_url=None, client_id=None)
```

Fetches the Profitability Waterlog table directly from the sheet. If `sheet_url` is provided the sheet ID (and GID) are resolved dynamically from that URL so each client sees data from their own sheet. Falls back to the hardcoded `SHEET_ID` / `WATERLOG_GID` when not supplied. Sheet structure (Profitability Waterlog tab): Col D/E : Bi-weekly period table — From, To Col F : Low (computed by Google Sheets from live trading data) Col G : High (computed by Google Sheets from live trading data) Low and High are read directly from columns F/G. Profit Split is recomputed using the `HWM/4` formula that matches the reference sheet. If `client_id` is provided, loads and applies any `split_pct_overrides` from the database, preventing the ratio-based detection from overwriting admin-set split percentages.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns `spct_overrides = {}`.
2. `if client_id:` branches conditionally.
3. Assigns `sid = _extract_sheet_id(sheet_url)` if `sheet_url` else `None`.
4. `if sid:` branches conditionally (with an `else/elif` arm).
5. Assigns `csv_content = get_sheet_csv(gid, sheet_id=sid)`.
6. `if not csv_content:` branches conditionally.
7. `try` block with 1 `except` clause.

Code (copy-paste safe)

```
def fetch_waterlog_data(sheet_url=None, client_id=None):
    """
    Fetches the Profitability Waterlog table directly from the sheet.

    If sheet_url is provided the sheet ID (and GID) are resolved dynamically
    from that URL so each client sees data from their own sheet.
    Falls back to the hardcoded SHEET_ID / WATERLOG_GID when not supplied.

    Sheet structure (Profitability Waterlog tab):
    Col D/E : Bi-weekly period table – From, To
    Col F    : Low (computed by Google Sheets from live trading data)
    Col G    : High (computed by Google Sheets from live trading data)

    Low and High are read directly from columns F/G. Profit Split is
    recomputed using the HWM/4 formula that matches the reference sheet.

    If client_id is provided, loads and applies any split_pct_overrides
    from the database, preventing the ratio-based detection from overwriting
    admin-set split percentages.

```

```
def fetch_waterlog_periods_from_sheet(sheet_url=None)
```

Reads the bi-weekly period schedule (columns D/E: From, To) from the sheet. Returns list of (from_date_str, to_date_str) in 'YYYY-MM-DD' format, filtered to valid dates (year 2000-2100). Used once during import to seed the waterlog_periods DB table.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns `sid = _extract_sheet_id(sheet_url)` if `sheet_url` else `None`.
2. **if** `sid`: branches conditionally (with an **else/elif** arm).
3. Assigns `csv_content = get_sheet_csv(gid, sheet_id=sid)`.
4. **if not** `csv_content`: branches conditionally.
5. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def fetch_waterlog_periods_from_sheet(sheet_url=None):
    """
    Reads the bi-weekly period schedule (columns D/E: From, To) from the sheet.
    Returns list of (from_date_str, to_date_str) in 'YYYY-MM-DD' format,
    filtered to valid dates (year 2000-2100).
    Used once during import to seed the waterlog_periods DB table.
    """
    sid = _extract_sheet_id(sheet_url) if sheet_url else None
    if sid:

def fetch_stats_data()
```

Fetches and parses the Stats tab.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `csv_content = get_sheet_csv(STATS_GID)`.
2. `if not csv_content:` branches conditionally.
3. `try` block with 1 **except** clause.

Code (copy-paste safe)

```

def fetch_stats_data():
    """Fetches and parses the Stats tab."""
    csv_content = get_sheet_csv(STATS_GID)
    if not csv_content:
        return None

    try:
        # Return raw rows for flexible rendering
        df = pd.read_csv(io.StringIO(csv_content), header=None)
        df = df.fillna('')
        return df.values.tolist()
    except Exception as e:
        logging.error(f"Error parsing Stats data: {e}")
        return None

```

Step 11.6 — Build dashboard/utils/trade_matcher.py

What to do. Create the file `dashboard/utils/trade_matcher.py` in your project root and paste in the code shown in this step. The file is **361** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

What this file is for. Reconciles MT5 deal history against the sheet's trade list to detect missing or duplicated entries.

dashboard/utils/trade_matcher.py

361 loc · 1 classes · 0 functions · 3 imports

Reconciles MT5 deal history against the sheet's trade list to detect missing or duplicated entries. It defines **1** class, across **361** lines.

Python concepts demonstrated in this module

• Classes and objects • Comprehensions • Dunder methods • Exceptions • f-strings • Lambdas

Imports — what each one is for

```
from datetime import datetime
```

Why imported. Dates, times, durations. The fundamental temporal types: `date`, `time`, `datetime`, `timedelta`, `timezone`.

Used in this file. `datetime`

Example. `datetime.now() - timedelta(days=7)` # one week ago

Other common scenarios.

- `datetime.strptime(s, '%Y-%m-%d')` parses a string
- `datetime.strftime(fmt)` formats one
- `datetime.fromtimestamp(n)` converts a Unix epoch
- `datetime.utcnow()` for UTC (better: `datetime.now(timezone.utc)`)

```
import re
```

Why imported. Regular expressions. Pattern matching, search, replace, and text extraction.

Used in this file. `re.search`, `re.sub`

Example. `re.search(r'\d{3}-\d{4}', text)` # returns a `Match` or `None`

Other common scenarios.

- `re.findall(pattern, text)` for every non-overlapping match
- `re.sub(pattern, repl, text)` to replace occurrences
- `re.compile(...)` to reuse a pattern (faster in a loop)

- Named groups: `r'(?P<year>\d{4})'` lets you do `m.group('year')`

`import logging`

Why imported. Structured, levelled logging. Replaces `print()` with filterable, formattable output that can route to files, stderr, syslog, or HTTP endpoints.

Used in this file. `logging.getLogger`

Example. `logging.getLogger(__name__).info('connected to %s', host)`

Other common scenarios.

- `.debug()` / `.info()` / `.warning()` / `.error()` / `.exception()`
- `logger.exception()` captures the current traceback automatically
- `logging.basicConfig(level=logging.INFO)` for quick setup
- Handlers and Formatters route logs to files / streams / syslog

Classes

`class UnifiedTradeMatcher`

Server-side logic to match MT5 deals to Dashboard Evaluation Rows. Solves the 'FundedNext Recycled Account' problem using Time-Based Session Grouping.

Code [\(copy-paste safe\)](#)

```

Method: UnifiedTradeMatcher.__init__

```
def __init__(self, evaluations)
```

Args: evaluations (list): List of evaluation dicts from dashboard_data.json

Why these Python concepts were used

- **__init__** — The constructor. Runs after Python has allocated the instance; assigns starting attribute values to self.

Step by step (top-level body)

1. Assigns self.evaluations = evaluations.
2. Assigns self.match_log = [].
3. Assigns self.account_map = self._build_account_map().

Code (copy-paste safe)

```

def __init__(self, evaluations):
    """
    Args:
        evaluations (list): List of evaluation dicts from dashboard_data.json
    """
    self.evaluations = evaluations
    self.match_log = []

    # Build optimized lookup maps
    self.account_map = self._build_account_map()

```

Method: UnifiedTradeMatcher._build_account_map

```
def _build_account_map(self)
```

Map Account Numbers -> List of (RowIndex, DatePurchasedObj, Type) Handles fuzzy matching (last 8-10 digits).

Why these Python concepts were used

- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns `lookup = {}`.
2. `for (idx, row) in enumerate(self.evaluations):` iterates.
3. `return lookup`.

Code (copy-paste safe)

```
def _build_account_map(self):
    """
    Map Account Numbers -> List of (RowIndex, DatePurchasedObj, Type)
    Handles fuzzy matching (last 8-10 digits).
    """
    lookup = {}

    for idx, row in enumerate(self.evaluations):
        # Parse Dates
        date_purchased = self._parse_date(row.get('Date Purchased'))
        date_started = self._parse_date(row.get('Date Started'))

        # Use Started date if available, else Purchased
        ref_date = date_started if date_started else date_purchased

        # 1. Challenge Account Check
        acct_ch = str(row.get('Account #', '')).strip()
        if acct_ch and acct_ch.lower() != 'nan':
            self._add_to_lookup(lookup, acct_ch, idx, ref_date, 'challenge')

        # 2. Funded Account Check
        acct_fu = str(row.get('Account #.1', '')).strip()
        if acct_fu and acct_fu.lower() != 'nan':
            self._add_to_lookup(lookup, acct_fu, idx, ref_date, 'funded')

    return lookup
```

Method: UnifiedTradeMatcher._add_to_lookup

```
def _add_to_lookup(self, lookup, account_str, idx, date, acct_type)
    Add account and its suffixes to lookup.
```

Why these Python concepts were used

- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to `sum`, `any`, `all`, or `max` where the intermediate list would be wasted.

Step by step (top-level body)

1. `if account_str not in lookup:` branches conditionally.
2. Calls `lookup[account_str].append(...)` for its side effect.
3. Assigns `clean_num = re.sub('[^0-9]', '', account_str)`.

4. if len(clean_num) > 5: branches conditionally.

Code (copy-paste safe)

```
def _add_to_lookup(self, lookup, account_str, idx, date, acct_type):
    """Add account and its suffixes to lookup."""
    # Clean account string (remove non-alphanumeric if needed, but usually keep as is)
    # Add full match
    if account_str not in lookup:
        lookup[account_str] = []
        lookup[account_str].append({'idx': idx, 'date': date, 'type': acct_type})

    # Add Suffix Matches (Last 8, 10, 12 digits)
    # Useful for 'FN-123456' vs '123456'
    clean_num = re.sub(r'^\0-9', '', account_str)
    if len(clean_num) > 5:
        for suffix_len in [8, 10, 12]:
            if len(clean_num) >= suffix_len:
                suffix = clean_num[-suffix_len:]
                # Only add if suffix distinct from full string
                if suffix != account_str:
                    if suffix not in lookup:
                        lookup[suffix] = []
                    # Avoid duplicates
                    if not any(x['idx'] == idx for x in lookup[suffix]):
                        lookup[suffix].append({'idx': idx, 'date': date, 'type': acct_type})
```

Method: UnifiedTradeMatcher._parse_date

```
def _parse_date(self, date_str)
    Parse 'MM/DD/YY' or ISO format to datetime object.
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

Step by step (top-level body)

1. if not date_str or str(date_str).lower() in ['none', 'nan', '']: branches conditionally.
2. try block with 1 **except** clause.

Code (copy-paste safe)

```
def _parse_date(self, date_str):
    """Parse 'MM/DD/YY' or ISO format to datetime object."""
    if not date_str or str(date_str).lower() in ['none', 'nan', '']:
        return None
    try:
        # Try MM/DD/YY (Dashboard format)
        return datetime.strptime(str(date_str).split('T')[0], "%m/%d/%y")
    except:
        try:
            # Try ISO
            return datetime.fromisoformat(str(date_str))
        except:
            try:
```

```

        # Try YYYY-MM-DD
        return datetime.strptime(str(date_str).split('T')[0], "%Y-%m-%d")
    except:
        return None

```

Method: UnifiedTradeMatcher.process_deals

```
def process_deals(self, deals)
```

Main entry point. 1. Parse Comments -> Get Account + Phase 2. Group by Session (Time-based) 3. Match Session to Best Dashboard Row 4. Update Rows Returns: updated_evaluations (list) log (list of strings)

Why these Python concepts were used

- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **if** not deals: branches conditionally.
2. Assigns parsed_deals = [].
3. **for** d in deals: iterates.
4. **if** not parsed_deals: branches conditionally.
5. Calls parsed_deals.sort(...) for its side effect.
6. Assigns deals_by_account = {}.
7. **for** pd in parsed_deals: iterates.
8. Assigns updates_count = 0.
9. **for** (acc_num, acc_deals) in deals_by_account.items(): iterates.
10. Calls self.match_log.append(...) for its side effect.
11. **return** (self.evaluations, self.match_log).

Code (copy-paste safe)

```

    # If client sends incremental, we might double count.
    # Requirement: "Client sends full history for relevant period".
    # We will overwrite based on the sum of provided deals. This is safer than adding to existing which

    for field, profit in field_sums.items():
        # Only update if changed significantly
        old_val = row.get(field)
        # Handle string conversions if necessary (dashboard usually uses strings or floats)
        row[field] = profit
        local_logs.append(f"    ■ Row {row_idx} {row.get('Account #')} [{field}] <- {profit:.2f}")
        updates += 1

    return updates, local_logs
```

Method: UnifiedTradeMatcher._get_field_name

```
def _get_field_name(self, phase, number)
```

Map Phase Code to Dashboard Column

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **if** phase == 'CH': branches conditionally (with an **else/elif** arm).
2. **return** None.

Code (copy-paste safe)

```
def _get_field_name(self, phase, number):
    """Map Phase Code to Dashboard Column"""
```

```

if phase == 'CH':
    if 1 <= number <= 5: return f"Hedge Result {number}"
elif phase == 'FD':
    if number == 0: return "Hedge Result 1.1" # FD0
    if 1 <= number <= 4: return f"Hedge Result {number + 1}.1" # FD1->2.1
    if number >= 5: return f"Hedge Result {number + 1}" # FD5->6
elif phase == 'FA':
    return "Hedge Day 1" # Simplification for Farming
return None

```

Method: UnifiedTradeMatcher._parse_deal_comment

```
def _parse_deal_comment(self, deal)
```

Extract {Account}_{Phase}{Num} Regex: ([A-Za-z0-9]+)_([CFD]+)([0-9]+) Ex: 123456_CH1 -> Account=123456, Phase=CH, Num=1

Step by step (top-level body)

1. Assigns comment = deal.get('comment', "").
2. if not comment: branches conditionally.
3. Assigns match = re.search('([A-Za-z0-9\-_]+)_([A-Z]{2})([0-9]+)', comment).
4. if match: branches conditionally.
5. Assigns match = re.search('([0-9]{5,})([A-Z]{2})([0-9]+)', comment).
6. if match: branches conditionally.
7. return None.

Code (copy-paste safe)

```

def _parse_deal_comment(self, deal):
    """
    Extract {Account}_{Phase}{Num}
    Regex: ([A-Za-z0-9]+)_([CFD]+)([0-9]+)
    Ex: 123456_CH1 -> Account=123456, Phase=CH, Num=1
    """
    comment = deal.get('comment', '')
    if not comment:
        return None

    # Try standard pattern
    # <Account>_<Phase><Num>
    # 123456_CH1
    # MFF123456_FD2
    match = re.search(r'([A-Za-z0-9\-\_]+)_([A-Z]{2})([0-9]+)', comment)
    if match:
        return {
            'account_number': match.group(1),
            'phase': match.group(2),
            'number': int(match.group(3))
        }

    # Try without underscore if failed (e.g. 123456CH1)
    match = re.search(r'([0-9]{5,})([A-Z]{2})([0-9]+)', comment)
    if match:
        return {
            'account_number': match.group(1),

```

```

        'phase': match.group(2),
        'number': int(match.group(3))
    }

    return None

```

Method: UnifiedTradeMatcher._parse_iso

```
def _parse_iso(self, date_str)
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

def _parse_iso(self, date_str):
    try:
        return datetime.fromisoformat(str(date_str).replace('Z', '+00:00'))
    except:
        return datetime.now()

```

Step 11.7 — Build dashboard/calc_like_sheet.py

What to do. Create the file dashboard/calc_like_sheet.py in your project root and paste in the code shown in this step. The file is **111** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from requirements.txt.

What this file is for. Replicates the formulas in the source-of-truth Google Sheet so the dashboard's numbers match what the trader sees in their sheet.

dashboard/calc_like_sheet.py

111 loc · 0 classes · 3 functions · 3 imports

Replicates the formulas in the source-of-truth Google Sheet so the dashboard's numbers match what the trader sees in their sheet. It defines **3** module-level functions, across **111** lines. Module docstring: *Calculate like the sheet: Completed vs In Progress*

Module docstring

Calculate like the sheet: Completed vs In Progress

Python concepts demonstrated in this module

- Comprehensions
- Exceptions
- f-strings

Imports — what each one is for

```
import pandas as pd
```

Why imported. DataFrame library — the workhorse for tabular data: loading CSV/Excel/SQL, joins, aggregations, time-series.

Used in this file. `pd.isna`, `pd.read_csv`

Example. `df = pd.read_csv(path); df.groupby('symbol')['pnl'].sum()`

Other common scenarios.

- `df.merge(other, on='key')` joins like SQL
- `df.resample('1D').agg(...)` for time-series rebucketing
- `df.to_sql` / `df.to_excel` / `df.to_parquet` for output
- `df.loc[mask, 'col']` for label-based selection/assignment

```
import requests
```

Why imported. The de-facto Python HTTP client. Synchronous; trades raw speed for an extremely friendly API.

Used in this file. `requests.get`

Example. `requests.get(url, timeout=10).json()`

Other common scenarios.

- `Session()` reuses TCP connections across calls
- `params=`, `headers=`, `json=`, `data=` for query/body shapes
- `raise_for_status()` turns 4xx/5xx into an exception
- `stream=True` for large downloads

```
from io import StringIO
```

Why imported. In-memory streams and the abstract base classes for file objects. Useful when an API expects a file but you only have bytes/text in memory.

Used in this file. `StringIO`

Example. `io.BytesIO(b'data')` # behaves like an open binary file

Other common scenarios.

- `io.StringIO('text')` for an in-memory text stream
- `io.TextIOWrapper` wraps a binary stream with an encoding

Module constants

Each line below is followed by a plain-English note explaining what it does and why it is written that way.

```
SHEET_URL = 'https://docs.google.com/spreadsheets/d/1rXdWErZD5C0pTWcAu8jCQSFbV2Mm1088cPoJHFauH2E/export?1
```

URL constant pointing to an external resource. Hard-coded at load time; change here, not in callers.

Functions

```
def parse_val(val)
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

Step by step (top-level body)

1. **if** `pd.isna(val)` or `val == ''` or `val == '-'`: branches conditionally.
2. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def parse_val(val):
    if pd.isna(val) or val == '' or val == '-':
        return 0.0
    try:
        clean = str(val).replace('$', '').replace(',', '').replace(' ', '')
        if clean == '' or clean == '-':
            return 0.0
        return float(clean)
    except:
        return 0.0
```

```
def is_completed(row)
```

Step by step (top-level body)

1. Assigns `status_p1 = str(row['Status P1']).strip().lower()`.
2. Assigns `status = str(row['Status']).strip().lower()`.
3. **return** `status_p1 == 'fail'` or `status` in `['fail', 'completed']`.

Code (copy-paste safe)

```
def is_completed(row):
    status_p1 = str(row['Status P1']).strip().lower()
    status = str(row['Status']).strip().lower()

    # Completed if:
    # - Status P1 is Fail (Phase 1 failed)
    # - OR Status is Fail/Completed (Funded phase ended)
    return status_p1 == 'fail' or status in ['fail', 'completed']

def calc_row_values(row)
```

Why these Python concepts were used

- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `fee = parse_val(row.get('Fee', 0)) + parse_val(row.get('Activat...`
2. Assigns `hedge_p1 = sum((parse_val(row.get(f'Hedge Result {i}', 0)) for i in ....`
3. Assigns `hedge_funded = sum((parse_val(row.get(col, 0)) for col in ['Hedge Result....`
4. Assigns `hedge_days = sum((parse_val(row.get(f'Hedge Day {i}', 0)) for i in ran....`
5. Assigns `total_hedge = hedge_p1 + hedge_funded + hedge_days.`
6. Assigns `payouts = sum((parse_val(row.get(f'Payout {i}', 0)) for i in range(...`
7. Assigns `farm = parse_val(row.get('Farming Net', 0)).`
8. **return** (`fee, total_hedge, payouts, farm`).

Code (copy-paste safe)

```
def calc_row_values(row):
    fee = parse_val(row.get('Fee', 0)) + parse_val(row.get('Activation Fee', 0))

    # Individual hedge results (NOT Hedge Net which is a calculated field)
    hedge_p1 = sum(parse_val(row.get(f'Hedge Result {i}', 0)) for i in range(1, 6))
    hedge_funded = sum(parse_val(row.get(col, 0)) for col in
        ['Hedge Result 1.1', 'Hedge Result 2.1', 'Hedge Result 3.1',
         'Hedge Result 4.1', 'Hedge Result 5.1', 'Hedge Result 6', 'Hedge Result 7'])
    hedge_days = sum(parse_val(row.get(f'Hedge Day {i}', 0)) for i in range(1, 51))

    total_hedge = hedge_p1 + hedge_funded + hedge_days

    payouts = sum(parse_val(row.get(f'Payout {i}', 0)) for i in range(1, 5))
    farm = parse_val(row.get('Farming Net', 0))

    return fee, total_hedge, payouts, farm
```

Step 11.8 — Build dashboard/phase_manager.py

What to do. Create the file `dashboard/phase_manager.py` in your project root and paste in the code shown in this step. The file is **242** lines long; we walk through it piece by piece below.

Depends on. This file imports from internal modules built in earlier steps: `database`. If any of those imports fail, jump back to the step that introduced them.

What this file is for. State machine that tracks each account's evaluation phase: `challenge`, `verification`, `funded`. Drives payout eligibility.

dashboard/phase_manager.py

242 loc · 1 classes · 0 functions · 4 imports

State machine that tracks each account's evaluation phase: challenge, verification, funded. Drives payout eligibility. It defines **1** class, across **242** lines.

Python concepts demonstrated in this module

• Classes and objects • @classmethod and @staticmethod • Context managers (with-statements) • Decorators • Exceptions • f-strings • Type hints

Imports — what each one is for

```
import json
```

Why imported. JSON encoding and decoding — the standard wire format for config files, API payloads, and inter-process messages.

Used in this file. `json.dumps`

Example. `json.loads(response.text)` # parse a JSON string to dict

Other common scenarios.

- `json.dumps(obj, indent=2)` for pretty-printing
- `json.dump(obj, file)` / `json.load(file)` for file I/O
- `default=str` handles non-serialisable types like `datetime`
- `object_hook=` customises decoding (e.g., to `dataclass` instances)

```
from datetime import datetime
from datetime import timedelta
```

Why imported. Dates, times, durations. The fundamental temporal types: `date`, `time`, `datetime`, `timedelta`, `timezone`.

Used in this file. `datetime`, `timedelta`

Example. `datetime.now() - timedelta(days=7)` # one week ago

Other common scenarios.

- `datetime.strptime(s, '%Y-%m-%d')` parses a string
- `datetime.strftime(fmt)` formats one
- `datetime.fromtimestamp(n)` converts a Unix epoch
- `datetime.utcnow()` for UTC (better: `datetime.now(timezone.utc)`)

```
from typing import Optional
from typing import Dict
from typing import List
from typing import Tuple
```

Why imported. Type-hint primitives — generics, unions, `Optional`, `Callable`, `Protocol`, `TypeVar`, `TypedDict`.

Used in this file. Dict, List, Optional

Example. `def lookup(k: str) -> Optional[int]: ...`

Other common scenarios.

- `List[int]` / `Dict[str, Any]` / `Tuple[int, str]` (or bare `list[int]`+ on 3.9+)
- `Callable[[int, int], int]` for function signatures
- Protocol for structural typing (duck typing with checks)
- `TypeVar('T')` for generic functions and classes

```
from .database import get_connection
```

Why imported. Sibling module — engine and session factory.

Used in this file. `get_connection`

Classes

```
class PhaseManager
```

Manages the lifecycle of trading phases (Challenge -> Funded -> Farming) using a deterministic, database-driven approach.

Code (copy-paste safe)

```
class PhaseManager:
    """
    Manages the lifecycle of trading phases (Challenge -> Funded -> Farming)
    using a deterministic, database-driven approach.
    """

    @staticmethod
    def initialize_default_phases():
        """Idempotently populates default phase definitions if they don't exist."""
        defaults = [
            # Challenge Phase 1
            {
                "phase_name": "Challenge Phase 1",
                "phase_code": "CH",
                "sequence_order": 1,

        return list(reversed(chain))

```

Method: PhaseManager.initialize_default_phases

```

@staticmethod
def initialize_default_phases()

    Idempotently populates default phase definitions if they don't exist.

```

Why these Python concepts were used

- **@staticmethod** — Declared **@staticmethod** because the function logically belongs in this class's namespace but does not depend on either the instance or the class — it is a pure helper that happens to be co-located with related code.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns defaults = [{'phase_name': 'Challenge Phase 1', 'phase_code': 'CH', ...
2. **with** get_connection(): enters a context manager.

Code (copy-paste safe)

```

def initialize_default_phases():
    """Idempotently populates default phase definitions if they don't exist."""
    defaults = [

```

```

# Challenge Phase 1
{
    "phase_name": "Challenge Phase 1",
    "phase_code": "CH",
    "sequence_order": 1,
    "ruleset": json.dumps({"type": "CHALLENGE", "target_percent": 0.08, "daily_loss": 0.05,
        "max_loss": 0.10}),
    "next_phase_code": "CH2" # Assuming 2-step challenge for now, or straight to FD

Method: PhaseManager.create_evaluation

```

@staticmethod
def create_evaluation(account_signature: str, phase_code: str, start_date: str, parent_id: Optional[int]=
    reset_id: Optional[str]=None) -> int

```

Creates a new evaluation record.

Why these Python concepts were used

- **@staticmethod** — Declared **@staticmethod** because the function logically belongs in this class's namespace but does not depend on either the instance or the class — it is a pure helper that happens to be co-located with related code.
- **type-annotated parameters** — Parameters carry type hints (e.g., `account_signature: str`, `phase_code: str`, `start_date: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> int`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **raise** — Raises an exception explicitly. Either signals an invalid argument the caller should fix, or re-raises after logging.

Step by step (top-level body)

1. **with get_connection():** enters a context manager.

Code (copy-paste safe)

```
def create_evaluation(
    account_signature: str,
    phase_code: str,
    start_date: str, # ISO Format YYYY-MM-DD
    parent_id: Optional[int] = None,
    reset_id: Optional[str] = None
) -> int:
    """
    Creates a new evaluation record.
    """
    with get_connection() as conn:
        cursor = conn.cursor()

        # Get validation rules from definition
        cursor.execute("SELECT sequence_order, ruleset FROM phase_definitions WHERE phase_code=?", (
            phase_code,))
        row = cursor.fetchone()
        if not row:
            raise ValueError(f"Unknown phase code: {phase_code}")

        phase_number = row[
            'sequence_order'] # Mapping sequence to phase_number for simplicity, or we can use auto-i

        # Use provided reset_id or inherit from parent
        final_reset_id = reset_id
        if not final_reset_id and parent_id:
            cursor.execute("SELECT reset_id FROM evaluations WHERE id=?", (parent_id,))
            parent = cursor.fetchone()
            if parent:
```

```

        final_reset_id = parent['reset_id']

    cursor.execute('''
        INSERT INTO evaluations
        (account_signature, phase_number, phase_type, status, start_date, parent_id, reset_id)
        VALUES (?, ?, ?, ?, ?, ?, ?)
    ''', (
        account_signature,
        phase_number,
        phase_code,
        'active',
        start_date,
        parent_id,
        final_reset_id
    ))
    conn.commit()
    return cursor.lastrowid

```

Method: PhaseManager.complete_phase

```

@staticmethod
def complete_phase(evaluation_id: int, status: str, end_date: str) -> Optional[int]

```

Marks a phase as completed/failed and triggers the next phase creation if successful. Returns the ID of the newly created next phase, or None.

Why these Python concepts were used

- **@staticmethod** — Declared **@staticmethod** because the function logically belongs in this class's namespace but does not depend on either the instance or the class — it is a pure helper that happens to be co-located with related code.
- **type-annotated parameters** — Parameters carry type hints (e.g., `evaluation_id: int`, `status: str`, `end_date: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> Optional[int]`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```

def complete_phase(evaluation_id: int, status: str, end_date: str) -> Optional[int]:
    """
    Marks a phase as completed/failed and triggers the next phase creation if successful.

```

Returns the ID of the newly created next phase, or None.
"""

```

        reset_id
    ))

    new_id = cursor.lastrowid
    conn.commit()
    return new_id

```

Method: PhaseManager.find_evaluation_for_trade

```

@staticmethod
def find_evaluation_for_trade(account_signature: str, trade_date_str: str) -> Optional[Dict]

```

Deterministic O(1) matching of trade to evaluation using Date Windows. trade_date_str: YYYY-MM-DD

Why these Python concepts were used

- **@staticmethod** — Declared **@staticmethod** because the function logically belongs in this class's namespace but does not depend on either the instance or the class — it is a pure helper that happens to be co-located with related code.
- **type-annotated parameters** — Parameters carry type hints (e.g., `account_signature: str`, `trade_date_str: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> Optional[Dict]`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns `trade_date_only = trade_date_str.split(' ')[0]` if `' '` in `trade_date_str` else....
2. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```

def find_evaluation_for_trade(account_signature: str, trade_date_str: str) -> Optional[Dict]:
    """
    Deterministic O(1) matching of trade to evaluation using Date Windows.
    trade_date_str: YYYY-MM-DD
    """
    # We need to handle datetime strings potentially including time
    # The prompt says: "start_date <= trade.close_date <= end_date"
    # We assume start/end dates in DB are YYYY-MM-DD.
    # Trade date might be YYYY-MM-DD HH:MM:SS.

```

```

trade_date_only = trade_date_str.split(' ')[0] if ' ' in trade_date_str else trade_date_str

with get_connection() as conn:
    cursor = conn.cursor()

    # Find evaluation where trade_date is >= start_date AND (end_date IS NULL OR trade_date <= end_date)
    # We treat NULL end_date as "Open/Active"
    cursor.execute('''
        SELECT * FROM evaluations
        WHERE account_signature = ?
        AND start_date <= ?
        AND (end_date IS NULL OR end_date >= ?)
        ORDER BY start_date DESC
        LIMIT 1
    ''', (account_signature, trade_date_only, trade_date_only))

    row = cursor.fetchone()
    if row:
        return dict(row)
    return None

```

Method: PhaseManager.get_phase_chain

```

@staticmethod
def get_phase_chain(latest_evaluation_id: int) -> List[Dict]

```

Traverses up the parent_id chain to get full history.

Why these Python concepts were used

- **@staticmethod** — Declared **@staticmethod** because the function logically belongs in this class's namespace but does not depend on either the instance or the class — it is a pure helper that happens to be co-located with related code.
- **type-annotated parameters** — Parameters carry type hints (e.g., latest_evaluation_id: int). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type -> List[Dict]. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. Assigns chain = [].
2. Assigns curr_id = latest_evaluation_id.
3. **with** get_connection(): enters a context manager.
4. **return** list(reversed(chain)).

Code (copy-paste safe)

```

def get_phase_chain(latest_evaluation_id: int) -> List[Dict]:
    """Traverses up the parent_id chain to get full history."""
    chain = []
    curr_id = latest_evaluation_id

```

```

with get_connection() as conn:
    cursor = conn.cursor()
    while curr_id:
        cursor.execute("SELECT * FROM evaluations WHERE id=?", (curr_id,))
        row = cursor.fetchone()
        if not row:
            break
        chain.append(dict(row))
        curr_id = row['parent_id']

return list(reversed(chain))

```

Step 11.9 — Build dashboard/watermark_service.py

What to do. Create the file dashboard/watermark_service.py in your project root and paste in the code shown in this step. The file is **688** lines long; we walk through it piece by piece below.

Depends on. This file imports from internal modules built in earlier steps: dashboard. If any of those imports fail, jump back to the step that introduced them.

What this file is for. Tracks high-water marks for accounts so that payout calculations only credit profit above the previous peak.

dashboard/watermark_service.py

688 loc · 0 classes · 22 functions · 3 imports

Tracks high-water marks for accounts so that payout calculations only credit profit above the previous peak. It defines **22** module-level functions, across **688** lines.

Python concepts demonstrated in this module

• Comprehensions • Context managers (with-statements) • Exceptions • f-strings • Lambdas

Imports — what each one is for

from dashboard.database import get_connection

Why imported. Internal package — the Flask dashboard. See chapter on dashboard/.

Used in this file. get_connection

from datetime import datetime
from datetime import timedelta

Why imported. Dates, times, durations. The fundamental temporal types: date, time, datetime, timedelta, timezone.

Used in this file. datetime, timedelta

Example. datetime.now() - timedelta(days=7) # one week ago

Other common scenarios.

- `datetime.strptime(s, '%Y-%m-%d')` parses a string
- `datetime.strftime(fmt)` formats one
- `datetime.fromtimestamp(n)` converts a Unix epoch
- `datetime.utcnow()` for UTC (better: `datetime.now(timezone.utc)`)

`import logging`

Why imported. Structured, levelled logging. Replaces `print()` with filterable, formattable output that can route to files, stderr, syslog, or HTTP endpoints.

Used in this file. `logging.error`, `logging.info`

Example. `logging.getLogger(__name__).info('connected to %s', host)`

Other common scenarios.

- `.debug()` / `.info()` / `.warning()` / `.error()` / `.exception()`
- `logger.exception()` captures the current traceback automatically
- `logging.basicConfig(level=logging.INFO)` for quick setup
- Handlers and Formatters route logs to files / streams / syslog

Functions

```
def save_daily_profit(client_id, net_profit, date_str=None, source='auto')
```

Saves or updates the daily net profit for a client. `date_str`: 'YYYY-MM-DD', defaults to today.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **if** not `date_str`: branches conditionally.
2. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def save_daily_profit(client_id, net_profit, date_str=None, source='auto'):
    """
    Saves or updates the daily net profit for a client.
    date_str: 'YYYY-MM-DD', defaults to today.
    """
    if not date_str:
        date_str = datetime.now().strftime('%Y-%m-%d')
```

```

try:
    with get_connection() as conn:
        cursor = conn.cursor()
        # Skip write if value hasn't changed for this date
        cursor.execute(
            'SELECT net_profit_complete FROM daily_watermarks WHERE client_id = ? AND date = ?',
            (client_id, date_str)
        )
        existing = cursor.fetchone()
        if existing and abs(float(existing['net_profit_complete']) - float(net_profit)) < 0.005:
            return True # Unchanged – skip write
        cursor.execute('''
            INSERT INTO daily_watermarks (client_id, date, net_profit_complete, source, created_at)
            VALUES (?, ?, ?, ?, CURRENT_TIMESTAMP)
            ON CONFLICT (client_id, date) DO UPDATE
            SET net_profit_complete = EXCLUDED.net_profit_complete,
                source = EXCLUDED.source,
                created_at = CURRENT_TIMESTAMP
            ''', (client_id, date_str, float(net_profit), source))
        conn.commit()
        logging.info(f"Saved daily watermark for {client_id} on {date_str}: ${net_profit} ({source}")
        return True
except Exception as e:
    logging.error(f"Error saving daily profit: {e}")
    return False

```

```
def get_watermark_history(client_id, days=30)
```

Returns list of dicts: [{'date': 'YYYY-MM-DD', 'profit': 123.45}, ...] Sorted by date.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **list comprehension** — Builds a list in a single expression ([f(x) for x in xs]). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

def get_watermark_history(client_id, days=30):
    """
    Returns list of dicts: [{'date': 'YYYY-MM-DD', 'profit': 123.45}, ...]
    Sorted by date.
    """
    try:
        cutoff_date = (datetime.now() - timedelta(days=days)).strftime('%Y-%m-%d')
        with get_connection() as conn:
            cursor = conn.cursor()

```

```

        cursor.execute('''
            SELECT date, net_profit_complete
            FROM daily_watermarks
            WHERE client_id = ? AND date >= ?
            ORDER BY date ASC
        ''', (client_id, cutoff_date))
        rows = cursor.fetchall()
        return [{'date': row['date'], 'profit': row['net_profit_complete']} for row in rows]
    except Exception as e:
        logging.error(f"Error getting watermark history: {e}")
        return []

```

```
def get_lower_watermark(client_id, days=14)
```

Returns the minimum profit recorded in the last X days. Returns: {'date': 'YYYY-MM-DD', 'profit': 123.45} or None

Why these Python concepts were used

- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.

Step by step (top-level body)

1. Assigns history = get_watermark_history(client_id, days).
2. **if** not history: branches conditionally.
3. Assigns min_record = min(history, key=lambda x: x['profit']).
4. **return** min_record.

Code (copy-paste safe)

```

def get_lower_watermark(client_id, days=14):
    """
    Returns the minimum profit recorded in the last X days.
    Returns: {'date': 'YYYY-MM-DD', 'profit': 123.45} or None
    """
    history = get_watermark_history(client_id, days)
    if not history:
        return None

    # Calculate min
    min_record = min(history, key=lambda x: x['profit'])
    return min_record

```

```
def get_high_watermark(client_id, days=14)
```

Returns the maximum profit recorded in the last X days. Returns: {'date': 'YYYY-MM-DD', 'profit': 123.45} or None

Why these Python concepts were used

- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.

Step by step (top-level body)

1. Assigns `history = get_watermark_history(client_id, days)`.
2. **if** not `history`: branches conditionally.
3. Assigns `max_record = max(history, key=lambda x: x['profit'])`.
4. **return** `max_record`.

Code (copy-paste safe)

```
def get_high_watermark(client_id, days=14):
    """
    Returns the maximum profit recorded in the last X days.
    Returns: {'date': 'YYYY-MM-DD', 'profit': 123.45} or None
    """
    history = get_watermark_history(client_id, days)
    if not history:
        return None

    # Calculate max
    max_record = max(history, key=lambda x: x['profit'])
    return max_record
```

```
def get_bulk_watermarks(days=14)
```

Returns a dictionary of watermarks for all clients over the last X days. Returns: {client_id: {'high': float, 'low': float}}

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def get_bulk_watermarks(days=14):
    """
    Returns a dictionary of watermarks for all clients over the last X days.
    Returns: {client_id: {'high': float, 'low': float}}
    """
    try:
        cutoff_date = (datetime.now() - timedelta(days=days)).strftime('%Y-%m-%d')
        with get_connection() as conn:
            cursor = conn.cursor()
            cursor.execute('''
                SELECT client_id, MAX(net_profit_complete) as high, MIN(net_profit_complete) as low
                FROM daily_watermarks
                WHERE date >= ?
                GROUP BY client_id
            ''')
```

```

'''', (cutoff_date,))
rows = cursor.fetchall()
# rows are usually tuples or dict-like depending on row_factory.
# Assuming sqlite3.Row or tuple.
result = {}
for row in rows:
    # row accessible by index if tuple, or key if Row.
    # standard sqlite3 without row_factory returns tuples.
    # But dashboard/database.py might set row_factory.
    # Let's assume keys work if Row, or index if tuple?
    # Safer: check type or try/except.
    # Actually, check get_connection implementation.
    try: # dict-like
        c_id = row['client_id']
        high = row['high']
        low = row['low']
    except: # tuple
        c_id = row[0]
        high = row[1]
        low = row[2]

    result[c_id] = {'high': high, 'low': low}
return result
except Exception as e:
    logging.error(f"Error getting bulk watermarks: {e}")
return {}

```

```
def get_aggregate_watermarks(days=14)
```

Returns the SUM of High and Low Watermarks for all clients (where individual values > 0) over the last X days. Returns: {'hwm': float, 'lwm': float}

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

def get_aggregate_watermarks(days=14):
    """
    Returns the SUM of High and Low Watermarks for all clients (where individual values > 0)
    over the last X days.
    Returns: {'hwm': float, 'lwm': float}
    """
    try:
        # Re-using get_bulk_watermarks to get individual HWM/LWM per client
        cutoff_date = (datetime.now() - timedelta(days=days)).strftime('%Y-%m-%d')

```

```

bulk_data = get_bulk_watermarks(days)

sum_hwm = 0.0
sum_lwm = 0.0

for client_id, metrics in bulk_data.items():
    h = metrics.get('high')
    l = metrics.get('low')

    except: l_val = 0.0

    if h_val > 0:
        sum_hwm += h_val

    if l_val > 0:
        sum_lwm += l_val

    return {
        'hwm': sum_hwm,
        'lwm': sum_lwm
    }
except Exception as e:
    logging.error(f"Error getting aggregate watermarks: {e}")
    return {'hwm': 0.0, 'lwm': 0.0}

```

```
def bulk_save_history(client_id, history_data)
```

Bulk saves history from external source (e.g., sheet). Overwrites all existing daily_watermarks for this client on each import. history_data: list of {'date': 'YYYY-MM-DD', 'profit': 123.45}

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

def bulk_save_history(client_id, history_data):
    """
    Bulk saves history from external source (e.g., sheet).
    Overwrites all existing daily_watermarks for this client on each import.

```

```

history_data: list of {'date': 'YYYY-MM-DD', 'profit': 123.45}
"""
try:
    with get_connection() as conn:
        cursor = conn.cursor()
        # Clear existing daily watermarks for this client then insert fresh
        cursor.execute('DELETE FROM daily_watermarks WHERE client_id = ?', (client_id,))
        for record in history_data:
            cursor.execute('''
                INSERT INTO daily_watermarks (client_id, date, net_profit_complete, source, created_at)

    return False

```

```
def get_waterlog_periods(client_id)
```

Returns the stored bi-weekly period schedule for a client. Returns: list of (from_date_str, to_date_str) sorted ascending.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **list comprehension** — Builds a list in a single expression ([f(x) for x in xs]). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

def get_waterlog_periods(client_id):
    """
    Returns the stored bi-weekly period schedule for a client.
    Returns: list of (from_date_str, to_date_str) sorted ascending.
    """
    try:
        with get_connection() as conn:
            cursor = conn.cursor()
            cursor.execute(

```

```

        'SELECT from_date, to_date FROM waterlog_periods WHERE client_id = ? ORDER BY from_date ASC'
        (client_id,)
    )
    return [(row['from_date'], row['to_date']) for row in cursor.fetchall()]
except Exception as e:
    logging.error(f"Error getting waterlog periods: {e}")
    return []

```

```
def get_waterlog_periods_with_values(client_id)
```

Returns the stored bi-weekly periods including sheet-imported Low/High/split_pct. Returns: list of dicts with from_date, to_date, period_low, period_high, split_pct

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

def get_waterlog_periods_with_values(client_id):
    """
    Returns the stored bi-weekly periods including sheet-imported Low/High/split_pct.
    Returns: list of dicts with from_date, to_date, period_low, period_high, split_pct
    """
    try:
        with get_connection() as conn:
            cursor = conn.cursor()
            cursor.execute(
                '''SELECT from_date, to_date, period_low, period_high, split_pct
                   FROM waterlog_periods WHERE client_id = ? ORDER BY from_date ASC''',
                (client_id,)
            )
            return [dict(row) for row in cursor.fetchall()]
    except Exception as e:
        logging.error(f"Error getting waterlog periods with values: {e}")
        return []

```

```
def get_all_daily_watermarks(client_id)
```

Returns ALL daily watermark rows for a client (no date cutoff). Returns: list of (date_obj, float)

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Lazy import from datetime.
2. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def get_all_daily_watermarks(client_id):
    """
    Returns ALL daily watermark rows for a client (no date cutoff).
    Returns: list of (date_obj, float)
    """
    from datetime import datetime as _dt
    try:
        with get_connection() as conn:
            cursor = conn.cursor()
            cursor.execute(
                'SELECT date, net_profit_complete FROM daily_watermarks WHERE client_id = ? ORDER BY date'
                (client_id,)
            )
            result = []
            for row in cursor.fetchall():
                try:
                    d = _dt.strptime(row['date'], '%Y-%m-%d').date()
                    result.append((d, float(row['net_profit_complete'])))
                except Exception:
                    pass
            return result
    except Exception as e:
        logging.error(f"Error getting all daily watermarks: {e}")
        return []
```

```
def get_client_split_pct(client_id)
```

Get the client's default profit split percentage. Policy: always 50% unless a per-period override exists in split_pct_overrides. Legacy values that may sit in identity.split_pct or waterlog_periods.split_pct (imported from sheets) are intentionally ignored — only explicit admin edits via /api/client/split_pct_override may deviate from the default. Returns int (50).

Step by step (top-level body)

1. **return** 50.

Code (copy-paste safe)

```
def get_client_split_pct(client_id):
    """Get the client's default profit split percentage.
    Policy: always 50% unless a per-period override exists in split_pct_overrides.
```

```

Legacy values that may sit in identity.split_pct or waterlog_periods.split_pct
(imported from sheets) are intentionally ignored – only explicit admin edits
via /api/client/split_pct_override may deviate from the default.
Returns int (50)."""
return 50

```

```
def compute_waterlog_from_db(client_id)
```

Computes the Profit Share History table entirely from DB data. For each period: - If period_low/period_high were stored at import time (from the sheet), those exact values are used — this keeps historical data identical to the Google Sheet. - For periods without stored values (new periods after import), Low/High are computed from daily_watermarks as min/max. Returns dict with 'periods' list and 'last_split_net_profit' float, or None if no periods are stored yet (triggers fall-back to sheet). Periods before 2/24/2026 use old HWM logic. Periods overlapping 2/24-3/20/2026 are condensed into one transition row. Periods after 3/20/2026 are generated monthly with new split logic: split = 50% of (current_net_profit - last_split_net_profit) if positive.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression ([f(x) for x in xs]). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Lazy import from datetime.
2. Assigns periods_with_vals = get_waterlog_periods_with_values(client_id).
3. if not periods_with_vals: branches conditionally.
4. Assigns daily = get_all_daily_watermarks(client_id).
5. Assigns TRANSITION_START = _date(2026, 2, 24).
6. Assigns TRANSITION_END = _date(2026, 3, 20).
7. Defines a nested function _fmt_date(...).
8. Defines a nested function _fmt_currency(...).
9. Calls periods_with_vals.sort(...) for its side effect.
10. Assigns np_overrides = get_net_profit_overrides(client_id).

11. Assigns `spct_overrides = get_split_pct_overrides(client_id)`.

12. Assigns `result = []`.

13. Assigns `hwm_low = 0.0`.

14. Assigns `last_pre_transition_net = 0.0`.

15. ... and 19 more statement(s) in the body.

Code (copy-paste safe)

```
def compute_waterlog_from_db(client_id):
    """

```
def _ensure_profit_split_overrides_table()
```

Create the profit_split_overrides table if it doesn't exist.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def _ensure_profit_split_overrides_table():
    """Create the profit_split_overrides table if it doesn't exist."""
    try:
        with get_connection() as conn:
            conn.execute('''
                CREATE TABLE IF NOT EXISTS profit_split_overrides (
                    client_id    TEXT NOT NULL,
                    from_date    TEXT NOT NULL,
                    amount        REAL NOT NULL,
                    updated_at    TIMESTAMP DEFAULT CURRENT_TIMESTAMP,
                    PRIMARY KEY (client_id, from_date)
                )
            ''')
            conn.commit()
    except Exception as e:
        logging.error(f"Error creating profit_split_overrides table: {e}")
```

```
def get_profit_split_overrides(client_id)
```

Return dict of from_date -> amount for all overrides for this client.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **dict comprehension** — Builds a dict in one expression (`{k: v for k, v in items}`) — same intent as a list comprehension but for mappings.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Calls `_ensure_profit_split_overrides_table(...)` for its side effect.
2. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def get_profit_split_overrides(client_id):
    """Return dict of from_date -> amount for all overrides for this client."""
    _ensure_profit_split_overrides_table()
    try:
        with get_connection() as conn:
            cursor = conn.cursor()
            cursor.execute(
                'SELECT from_date, amount FROM profit_split_overrides WHERE client_id = ?',
                (client_id,)
            )
            return {row['from_date']: float(row['amount']) for row in cursor.fetchall()}
    except Exception as e:
```

```
logging.error(f"Error loading profit split overrides: {e}")
return {}
```

```
def save_profit_split_override(client_id, from_date, amount)
```

Save or update a profit split override for a specific period.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Calls `_ensure_profit_split_overrides_table(...)` for its side effect.
2. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def save_profit_split_override(client_id, from_date, amount):
    """Save or update a profit split override for a specific period."""
    _ensure_profit_split_overrides_table()
    try:
        with get_connection() as conn:
            conn.execute('''
                INSERT INTO profit_split_overrides (client_id, from_date, amount, updated_at)
                VALUES (?, ?, ?, CURRENT_TIMESTAMP)
                ON CONFLICT (client_id, from_date) DO UPDATE
                SET amount = EXCLUDED.amount,
                    updated_at = CURRENT_TIMESTAMP
            ''', (client_id, from_date, float(amount)))
            conn.commit()
            logging.info(f"Saved profit split override for {client_id} period {from_date}: ${amount}")
            return True
    except Exception as e:
        logging.error(f"Error saving profit split override: {e}")
        return False
```

```
def _ensure_net_profit_overrides_table()
```

Create the net_profit_overrides table if it doesn't exist.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def _ensure_net_profit_overrides_table():
    """Create the net_profit_overrides table if it doesn't exist."""
    try:
        with get_connection() as conn:
            conn.execute('''
                CREATE TABLE IF NOT EXISTS net_profit_overrides (
                    client_id    TEXT NOT NULL,
                    from_date    TEXT NOT NULL,
                    amount        REAL NOT NULL,
                    updated_at    TIMESTAMP DEFAULT CURRENT_TIMESTAMP,
                    PRIMARY KEY (client_id, from_date)
                )
            ''')
            conn.commit()
    except Exception as e:
        logging.error(f"Error creating net_profit_overrides table: {e}")
```

```
def get_net_profit_overrides(client_id)
```

Return dict of from_date -> amount for all net profit overrides for this client.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **dict comprehension** — Builds a dict in one expression (`{k: v for k, v in items}`) — same intent as a list comprehension but for mappings.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Calls `_ensure_net_profit_overrides_table(...)` for its side effect.
2. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def get_net_profit_overrides(client_id):
    """Return dict of from_date -> amount for all net profit overrides for this client."""
    _ensure_net_profit_overrides_table()
    try:
        with get_connection() as conn:
            cursor = conn.cursor()
            cursor.execute(
```

```

        'SELECT from_date, amount FROM net_profit_overrides WHERE client_id = ?',
        (client_id,)
    )
    return {row['from_date']: float(row['amount']) for row in cursor.fetchall()}
except Exception as e:
    logging.error(f"Error loading net profit overrides: {e}")
    return {}

```

```
def save_net_profit_override(client_id, from_date, amount)
```

Save or update a net profit override for a specific period.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Calls `_ensure_net_profit_overrides_table(...)` for its side effect.
2. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

def save_net_profit_override(client_id, from_date, amount):
    """Save or update a net profit override for a specific period."""
    _ensure_net_profit_overrides_table()
    try:
        with get_connection() as conn:
            conn.execute('''
                INSERT INTO net_profit_overrides (client_id, from_date, amount, updated_at)
                VALUES (?, ?, ?, CURRENT_TIMESTAMP)
                ON CONFLICT (client_id, from_date) DO UPDATE
                SET amount = EXCLUDED.amount,
                    updated_at = CURRENT_TIMESTAMP
            ''', (client_id, from_date, float(amount)))
            conn.commit()
            logging.info(f"Saved net profit override for {client_id} period {from_date}: ${amount}")
            return True
    except Exception as e:
        logging.error(f"Error saving net profit override: {e}")
        return False

```

```
def _ensure_split_pct_overrides_table()
```

Create the split_pct_overrides table if it doesn't exist.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't

have to handle it.

- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def _ensure_split_pct_overrides_table():
    """Create the split_pct_overrides table if it doesn't exist."""
    try:
        with get_connection() as conn:
            conn.execute('''
                CREATE TABLE IF NOT EXISTS split_pct_overrides (
                    client_id    TEXT NOT NULL,
                    from_date    TEXT NOT NULL,
                    pct          REAL NOT NULL,
                    updated_at    TIMESTAMP DEFAULT CURRENT_TIMESTAMP,
                    PRIMARY KEY (client_id, from_date)
                )
            ''')
            conn.commit()
    except Exception as e:
        logging.error(f"Error creating split_pct_overrides table: {e}")

def get_split_pct_overrides(client_id)
    """Return dict of from_date -> pct for all split percentage overrides for this client.
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **dict comprehension** — Builds a dict in one expression (`{k: v for k, v in items}`) — same intent as a list comprehension but for mappings.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Calls `_ensure_split_pct_overrides_table(...)` for its side effect.
2. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def get_split_pct_overrides(client_id):
    """Return dict of from_date -> pct for all split percentage overrides for this client."""
```

```

_ensure_split_pct_overrides_table()
try:
    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute(
            'SELECT from_date, pct FROM split_pct_overrides WHERE client_id = ?',
            (client_id,)
        )
        return {row['from_date']: float(row['pct']) for row in cursor.fetchall()}
except Exception as e:
    logging.error(f"Error loading split pct overrides: {e}")
    return {}

```

```
def save_split_pct_override(client_id, from_date, pct)
```

Save or update a split percentage override for a specific period.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Calls `_ensure_split_pct_overrides_table(...)` for its side effect.
2. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

def save_split_pct_override(client_id, from_date, pct):
    """Save or update a split percentage override for a specific period."""
    _ensure_split_pct_overrides_table()
    try:
        pct = float(pct)
        if pct < 0 or pct > 100:
            logging.error(f"Invalid split_pct value {pct} – must be 0-100")
            return False
        with get_connection() as conn:
            conn.execute('''
                INSERT INTO split_pct_overrides (client_id, from_date, pct, updated_at)
                VALUES (?, ?, ?, CURRENT_TIMESTAMP)
                ON CONFLICT (client_id, from_date) DO UPDATE
                SET pct = EXCLUDED.pct,
                    updated_at = CURRENT_TIMESTAMP
            ''', (client_id, from_date, pct))
            conn.commit()
            logging.info(f"Saved split pct override for {client_id} period {from_date}: {pct}%")
            return True
    except Exception as e:
        logging.error(f"Error saving split pct override: {e}")
        return False

```

Step 11.10 — Build dashboard/financial_overview.py

What to do. Create the file dashboard/financial_overview.py in your project root and paste in the code shown in this step. The file is **1718** lines long; we walk through it piece by piece below.

Depends on. This file imports from internal modules built in earlier steps: dashboard. If any of those imports fail, jump back to the step that introduced them.

What this file is for. Aggregates deposits, withdrawals, fees, and payouts into the Financial Overview tab the admin dashboard renders.

dashboard/financial_overview.py

1718 loc · 1 classes · 24 functions · 6 imports

Aggregates deposits, withdrawals, fees, and payouts into the Financial Overview tab the admin dashboard renders. It defines **1** class and **24** module-level functions, across **1,718** lines.

Python concepts demonstrated in this module

• Classes and objects • Comprehensions • Decorators • Dunder methods • Exceptions • f-strings • Module-level state • Lambdas

Imports — what each one is for

```
from dashboard.database import get_all_clients
```

Why imported. Internal package — the Flask dashboard. See chapter on dashboard/.

Used in this file. get_all_clients

```
import re
```

Why imported. Regular expressions. Pattern matching, search, replace, and text extraction.

Used in this file. *No direct attribute access detected — likely imported for side effects, re-export, or string references.*

Example. re.search(r'\d{3}-\d{4}', text) # returns a Match or None

Other common scenarios.

- re.findall(pattern, text) for every non-overlapping match
- re.sub(pattern, repl, text) to replace occurrences
- re.compile(...) to reuse a pattern (faster in a loop)
- Named groups: r'(?P<year>\d{4})' lets you do m.group('year')

```
from datetime import datetime
from datetime import timedelta
```

Why imported. Dates, times, durations. The fundamental temporal types: date, time, datetime, timedelta, timezone.

Used in this file. datetime

Example. datetime.now() - timedelta(days=7) # one week ago

Other common scenarios.

- datetime.strptime(s, '%Y-%m-%d') parses a string
- datetime.strftime(fmt) formats one
- datetime.fromtimestamp(n) converts a Unix epoch
- datetime.utcnow() for UTC (better: datetime.now(timezone.utc))

```
import json
```

Why imported. JSON encoding and decoding — the standard wire format for config files, API payloads, and inter-process messages.

Used in this file. json.loads

Example. json.loads(response.text) # parse a JSON string to dict

Other common scenarios.

- json.dumps(obj, indent=2) for pretty-printing
- json.dump(obj, file) / json.load(file) for file I/O
- default=str handles non-serialisable types like datetime
- object_hook= customises decoding (e.g., to dataclass instances)

```
import functools
```

Why imported. Higher-order helpers — caching, partial application, decorator authoring tools, reducers.

Used in this file. functools.wraps

Example. @lru_cache(maxsize=128) # memoise this pure function

Other common scenarios.

- partial(f, x=1) pre-binds arguments
- reduce(f, iterable) folds an iterable to a single value
- @wraps(fn) preserves __name__ / __doc__ when writing decorators
- @cached_property memoises a property per-instance

```
import time
```

Why imported. Timestamps and sleep. Lower-level than datetime — works in Unix-epoch seconds.

Used in this file. time.time

Example. time.sleep(1.5) # pause this thread for 1.5 seconds

Other common scenarios.

- time.time() returns seconds since the epoch

- `time.monotonic()` for measuring elapsed time (never goes backward)
- `time.perf_counter()` for high-precision benchmarking
- `time.strftime` / `time.strptime` mirror the `datetime` versions

Classes

```
class SimpleCache
```

Code (copy-paste safe)

```
class SimpleCache:
    def __init__(self, max_keys=50):
        self._cache = {}
        self._ttl = 300 # 5 minutes default
        self._max_keys = max_keys

    def get(self, key):
        if key in self._cache:
            data, expiry = self._cache[key]
            if time.time() < expiry:
                return data
            else:
                del self._cache[key]
        return None

    def set(self, key, value, ttl=None):
        # Evict expired entries first, then oldest if still over limit
        if len(self._cache) >= self._max_keys:
            self._evict()
        expiration = time.time() + (ttl or self._ttl)
        self._cache[key] = (value, expiration)

    def _evict(self):
        now = time.time()
        # Remove expired entries
        expired = [k for k, (_, exp) in self._cache.items() if now >= exp]
        for k in expired:
            del self._cache[k]
        # If still over limit, remove oldest entries
        while len(self._cache) >= self._max_keys:
            oldest_key = min(self._cache, key=lambda k: self._cache[k][1])
            del self._cache[oldest_key]

    def clear(self):
        self._cache = {}
```

Method: `SimpleCache.__init__`

```
def __init__(self, max_keys=50)
```

Why these Python concepts were used

- `__init__` — The constructor. Runs after Python has allocated the instance; assigns starting attribute values to `self`.

Step by step (top-level body)

1. Assigns `self._cache = {}`.

2. Assigns `self._ttl = 300`.
3. Assigns `self._max_keys = max_keys`.

Code (copy-paste safe)

```
def __init__(self, max_keys=50):
    self._cache = {}
    self._ttl = 300 # 5 minutes default
    self._max_keys = max_keys
```

Method: SimpleCache.get

```
def get(self, key)
```

Step by step (top-level body)

1. if `key in self._cache`: branches conditionally.
2. `return None`.

Code (copy-paste safe)

```
def get(self, key):
    if key in self._cache:
        data, expiry = self._cache[key]
        if time.time() < expiry:
            return data
        else:
            del self._cache[key]
    return None
```

Method: SimpleCache.set

```
def set(self, key, value, ttl=None)
```

Step by step (top-level body)

1. if `len(self._cache) >= self._max_keys`: branches conditionally.
2. Assigns `expiration = time.time() + (ttl or self._ttl)`.
3. Assigns `self._cache[key] = (value, expiration)`.

Code (copy-paste safe)

```
def set(self, key, value, ttl=None):
    # Evict expired entries first, then oldest if still over limit
    if len(self._cache) >= self._max_keys:
        self._evict()
    expiration = time.time() + (ttl or self._ttl)
    self._cache[key] = (value, expiration)
```

Method: SimpleCache._evict

```
def _evict(self)
```

Why these Python concepts were used

- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with `append`, and clearer about intent: this is a transform, not a side-effecting loop.
- **lambda** — Uses a single-expression anonymous function — typically as the `key=` for a sort, the filter predicate, or a small callback.

Step by step (top-level body)

1. Assigns `now = time.time()`.
2. Assigns `expired = [k for k, (_, exp) in self._cache.items() if now >= exp]`.
3. **for** `k` in `expired`: iterates.
4. **while** `len(self._cache) >= self._max_keys`: loops until the condition is false.

Code (copy-paste safe)

```
def _evict(self):
    now = time.time()
    # Remove expired entries
    expired = [k for k, (_, exp) in self._cache.items() if now >= exp]
    for k in expired:
        del self._cache[k]
    # If still over limit, remove oldest entries
    while len(self._cache) >= self._max_keys:
        oldest_key = min(self._cache, key=lambda k: self._cache[k][1])
        del self._cache[oldest_key]
```

Method: SimpleCache.clear

```
def clear(self)
```

Step by step (top-level body)

1. Assigns `self._cache = {}`.

Code (copy-paste safe)

```
def clear(self):
    self._cache = {}
```

Functions

```
def col_idx_to_letter(n)
```

Converts 0-based column index to Excel-style column letters. 0 -> A, 1 -> B, 25 -> Z, 26 -> AA, 27 -> AB

Step by step (top-level body)

1. Assigns `res = ""`.
2. **while** `n >= 0`: loops until the condition is false.
3. **return** `res`.

Code (copy-paste safe)

```
def col_idx_to_letter(n):
    """
    Converts 0-based column index to Excel-style column letters.
```

```

0 -> A, 1 -> B, 25 -> Z, 26 -> AA, 27 -> AB
"""
res = ""
while n >= 0:
    res = chr(ord('A') + (n % 26)) + res
    n = (n // 26) - 1
return res

```

```
def cache_result(ttl=300)
```

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.

Step by step (top-level body)

1. Defines a nested function decorator(...).
2. **return** decorator.

Code (copy-paste safe)

```

def cache_result(ttl=300):
    def decorator(func):
        @functools.wraps(func)
        def wrapper(*args, **kwargs):
            # Create a cache key based on function name and arguments
            key = f"{func.__name__}:{str(args)}:{str(kwargs)}"
            cached = _overview_cache.get(key)
            if cached is not None:
                return cached

            result = func(*args, **kwargs)
            _overview_cache.set(key, result, ttl)
            return result
        return wrapper
    return decorator

```

```

@cache_result(ttl=10)
def _get_cached_clients()

    Cached wrapper for database.get_all_clients

```

Why these Python concepts were used

- **@cache_result** — Memoises return values keyed by the arguments. Trades memory for speed when the function is pure and called many times with the same inputs.

Step by step (top-level body)

1. **return** get_all_clients().

Code (copy-paste safe)

```
def _get_cached_clients():
```

```

    """Cached wrapper for database.get_all_clients"""
    return get_all_clients()

```

```
def _get_hierarchy_profile_map()
```

Build a {client_name: category} map from the hierarchy JSON (cached 60s).

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **global** — Rebinds a module-level name from inside the function. A smell in larger codebases — usually means a singleton or cache that could be passed in instead.

Step by step (top-level body)

1. Declares globals: `_hierarchy_profile_cache`, `_hierarchy_profile_cache_time`.
2. `if _hierarchy_profile_cache and time.time() - _hierarchy_profile_cache_time < 60:` branches conditionally.
3. `try` block with 1 **except** clause.
4. Assigns `profile_map = {}`.
5. `if SYSTEM_HIERARCHY and 'admins' in SYSTEM_HIERARCHY:` branches conditionally.
6. Assigns `_hierarchy_profile_cache = profile_map`.
7. Assigns `_hierarchy_profile_cache_time = time.time()`.
8. `return profile_map`.

Code (copy-paste safe)

```

def _get_hierarchy_profile_map():
    """Build a {client_name: category} map from the hierarchy JSON (cached 60s)."""
    global _hierarchy_profile_cache, _hierarchy_profile_cache_time
    if _hierarchy_profile_cache and (time.time() - _hierarchy_profile_cache_time) < 60:
        return _hierarchy_profile_cache
    try:
        from config.hierarchy import SYSTEM_HIERARCHY
    except ImportError:
        return {}
    profile_map = {}
    if SYSTEM_HIERARCHY and 'admins' in SYSTEM_HIERARCHY:
        for admin_data in SYSTEM_HIERARCHY['admins'].values():
            for trader_data in admin_data.get('traders', {}).values():
                for client in trader_data.get('clients', []):
                    c_name = client.get('name')
                    cat = (client.get('category') or '').upper()
                    if c_name and cat:
                        profile_map[c_name] = cat
    _hierarchy_profile_cache = profile_map
    _hierarchy_profile_cache_time = time.time()
    return profile_map

```

```
def get_client_profile(client_id, identity=None)
```

Resolve client profile: check identity fields first, then hierarchy category, default PRIVATE.

Why these Python concepts were used

- **ternary expression** — Uses `x` if `cond` else `y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **if** `identity`: branches conditionally.
2. Assigns `h_map = _get_hierarchy_profile_map()`.
3. Assigns `real_name = identity.get('name') if identity else None`.
4. **if** `real_name` and `real_name` in `h_map`: branches conditionally.
5. **if** `client_id` in `h_map`: branches conditionally.
6. **return** `'PRIVATE'`.

Code (copy-paste safe)

```
def get_client_profile(client_id, identity=None):
    """Resolve client profile: check identity fields first, then hierarchy category, default PRIVATE."""
    if identity:
        p = (identity.get('profile') or identity.get('category') or identity.get('source') or '').upper()
        if p:
            return p
    # Fallback: check hierarchy
    h_map = _get_hierarchy_profile_map()
    real_name = identity.get('name') if identity else None
    if real_name and real_name in h_map:
        return h_map[real_name]
    if client_id in h_map:
        return h_map[client_id]
    return 'PRIVATE'
```

```
def parse_currency(value_str)
```

Parses a currency string like "\$120.65", "1,200.00", "-", "\$ -" into a float. Returns 0.0 if the value is missing or represents zero.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.

Step by step (top-level body)

1. **if** `value_str` is `None`: branches conditionally.
2. **if** `isinstance(value_str, (int, float))`: branches conditionally.
3. **if not** `isinstance(value_str, str)`: branches conditionally.
4. Assigns `clean_str = value_str.replace('$', '').replace(',', '').strip()`.
5. **if not** `clean_str` or `clean_str` in `['-', 'n/a', 'null']`: branches conditionally.

6. try block with 1 except clause.

Code (copy-paste safe)

```
def parse_currency(value_str):
    """
    Parses a currency string like "$120.65", "1,200.00", "-", "$ -" into a float.
    Returns 0.0 if the value is missing or represents zero.
    """
    if value_str is None:
        return 0.0
    if isinstance(value_str, (int, float)):
        return float(value_str)

    if not isinstance(value_str, str):
        return 0.0

    # Remove $ and , and spaces
    clean_str = value_str.replace('$', '').replace(',', '').strip()

    if not clean_str or clean_str in ['- ', '\n/a', 'null']:
        return 0.0

    try:
        # Handle parentheses for negative numbers, e.g. (100) -> -100
        if clean_str.startswith('(') and clean_str.endswith(')'):
            return -float(clean_str[1:-1])
        return float(clean_str)
    except ValueError:
        return 0.0

def clear_financial_cache()
```

Invalidate the financial overview cache.

Step by step (top-level body)

1. Calls `_overview_cache.clear(...)` for its side effect.

Code (copy-paste safe)

```
def clear_financial_cache():
    """Invalidate the financial overview cache."""
    _overview_cache.clear()

@cache_result(ttl=30)
def calculate_all_financials(profile_filter=None, start_date=None, end_date=None)
```

Optimized aggregator that computes all financial metrics in a single pass. Returns a dictionary containing all necessary datasets for the dashboard. Optionally filters by start_date and end_date (datetime objects).

Why these Python concepts were used

- **@cache_result** — Memoises return values keyed by the arguments. Trades memory for speed when the function is pure and called many times with the same inputs.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't

have to handle it.

- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to `sum`, `any`, `all`, or `max` where the intermediate list would be wasted.
- **lambda** — Uses a single-expression anonymous function — typically as the `key=` for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

```

```
def parse_date(date_str)
```

Parses date string to datetime object.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.

Step by step (top-level body)

1. **if** not `date_str` or not `isinstance(date_str, str)`: branches conditionally.
2. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

def parse_date(date_str):
    """Parses date string to datetime object."""
    if not date_str or not isinstance(date_str, str):
        return None
    try:
        # Try MM/DD/YY
        return datetime.strptime(date_str.strip(), "%m/%d/%y")
    except ValueError:
        try:
            # Try YYYY-MM-DD
            return datetime.strptime(date_str.strip(), "%Y-%m-%d")
        except ValueError:
            return None

```

```
def get_payouts_history(start_date=None, end_date=None, prop_firm_filter=None, profile_filter=None)
```

Returns a list of all payouts with details.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **try** block with 1 **except** clause.
2. Assigns `client_map = {}`.
3. **if** `SYSTEM_HIERARCHY` and `'admins'` in `SYSTEM_HIERARCHY`: branches conditionally.
4. Assigns `clients_data = _get_cached_clients()`.
5. Assigns `payouts_list = []`.
6. **for** `(client_id, data)` in `clients_data.items()`: iterates.
7. Calls `payouts_list.sort(...)` for its side effect.
8. **return** `payouts_list`.

Code (copy-paste safe)

```
def get_payouts_history(start_date=None, end_date=None, prop_firm_filter=None, profile_filter=None):
    """
    Returns a list of all payouts with details.
    """
    # Import hierarchy to map clients to traders/admins

@cache_result(ttl=300)
def get_portfolio_growth_data(profile_filter=None)

```

Calculates cumulative portfolio growth over time. Returns lists of labels (dates) and data points (net profit).

Why these Python concepts were used

- **@cache_result** — Memoises return values keyed by the arguments. Trades memory for speed when the function is pure and called many times with the same inputs.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.

Step by step (top-level body)

1. Assigns `clients_data = _get_cached_clients()`.
2. Assigns `events = []`.
3. **for** `(client_id, data)` in `clients_data.items()`: iterates.
4. Calls `events.sort(...)` for its side effect.
5. **if not** `events`: branches conditionally.
6. Assigns `dates = []`.
7. Assigns `values = []`.
8. Assigns `cumulative = 0.0`.
9. Lazy import from `collections`.
10. Assigns `daily_changes = defaultdict(float)`.
11. **for** `(date_obj, amount)` in `events`: iterates.
12. Assigns `sorted_days = sorted(daily_changes.keys())`.
13. **for** `day` in `sorted_days`: iterates.
14. **return** `(dates, values)`.

@cache_result(ttl=300)
def calculate_propfirm_overview(profile_filter=None)
    Aggregates financial data by Prop Firm. Returns a dictionary.

```

Why these Python concepts were used

- **@cache_result** — Memoises return values keyed by the arguments. Trades memory for speed when the function is pure and called many times with the same inputs.

- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

        events.append((date_ended_funded or date_ended or base_date, farming_calc))

return _aggregate_events_cumulative(events)

```

```
def _aggregate_events_cumulative(events)
```

Why these Python concepts were used

- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.

Step by step (top-level body)

1. **if** not events: branches conditionally.
2. Calls events.sort(...) for its side effect.
3. Lazy import from collections.
4. Assigns daily_changes = defaultdict(float).
5. **for** (dt, val) in events: iterates.
6. Assigns dates = [].
7. Assigns values = [].
8. Assigns cumulative = 0.0.
9. Assigns sorted_days = sorted(daily_changes.keys()).
10. **for** day in sorted_days: iterates.
11. **return** (dates, values).

Code (copy-paste safe)

```

def _aggregate_events_cumulative(events):
    if not events:
        return [], []

    events.sort(key=lambda x: x[0])

    from collections import defaultdict
    daily_changes = defaultdict(float)

    for dt, val in events:
        d_str = dt.strftime("%Y-%m-%d")
        daily_changes[d_str] += val

    dates = []

```

```

values = []
cumulative = 0.0
sorted_days = sorted(daily_changes.keys())

for day in sorted_days:
    cumulative += daily_changes[day]
    dates.append(day)
    values.append(cumulative)

return dates, values

```

```
def calculate_trader_stats(profile_filter=None)
```

Calculates aggregated statistics per trader.

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns `clients_data = _get_cached_clients()`.
2. Assigns `traders_stats = {}`.
3. **for** `(client_id, data) in clients_data.items()`: iterates.
4. **return** `list(traders_stats.values())`.

Code (copy-paste safe)

```

def calculate_trader_stats(profile_filter=None):

return list(traders_stats.values())

@cache_result(ttl=300)
def get_client_performance_stats(profile_filter=None, start_date=None, end_date=None)

    Returns a list of per-client performance statistics. Used for the Client Performance Table. Optionally
    filters by start_date and end_date (datetime objects).

```

Why these Python concepts were used

- **@cache_result** — Memoises return values keyed by the arguments. Trades memory for speed when the function is pure and called many times with the same inputs.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **set comprehension** — Builds a set in one expression — usually to deduplicate the result of a transform.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns BEF_HIDDEN_FIRMS = {'lucid', 'apex', 'tradeday', 'toponefutures'}.
2. Assigns is_bef = profile_filter and profile_filter.upper() == 'BEF'.
3. Defines a nested function _is_firm_hidden(...).
4. **try** block with 1 **except** clause.
5. Assigns client_map = {}.
6. **if** SYSTEM_HIERARCHY and 'admins' in SYSTEM_HIERARCHY: branches conditionally.
7. Assigns clients_data = _get_cached_clients().
8. Assigns clients_list = [].
9. **for** (client_id, data) in clients_data.items(): iterates.
10. Assigns seen_clients = {c['client_id'] for c in clients_list}.
11. **try** block with 1 **except** clause.
12. **if** h and 'admins' in h: branches conditionally.
13. **return** clients_list.

Step 11.11 — Build dashboard/scheduler.py

What to do. Create the file dashboard/scheduler.py in your project root and paste in the code shown in this step. The file is **605** lines long; we walk through it piece by piece below.

Depends on. This file imports from internal modules built in earlier steps: dashboard. If any of those imports fail, jump back to the step that introduced them.

What this file is for. APScheduler setup. Cron-style jobs that resync from Google Sheets, recompute statistics, and send notifications.

dashboard/scheduler.py

605 loc · 0 classes · 12 functions · 10 imports

APScheduler setup. Cron-style jobs that resync from Google Sheets, recompute statistics, and send notifications. It defines **12** module-level functions, across **605** lines.

Python concepts demonstrated in this module

- Comprehensions
- Context managers (with-statements)
- Exceptions
- f-strings
- Module-level state
- Lambdas

Imports — what each one is for

```
import threading
```

Why imported. Threads and synchronisation primitives. Used when work is I/O-bound and the GIL is not a bottleneck (the GIL prevents speed-up on CPU-bound work).

Used in this file. threading.Event, threading.Lock, threading.Thread

Example. Thread(target=worker, args=(q,), daemon=True).start()

Other common scenarios.

- Lock / RLock to guard shared state

- Event for one-shot signals between threads
- Queue (from queue) for producer/consumer patterns
- threading.local() for thread-local storage

`import time`

Why imported. Timestamps and sleep. Lower-level than datetime — works in Unix-epoch seconds.

Used in this file. `time.sleep`

Example. `time.sleep(1.5)` # pause this thread for 1.5 seconds

Other common scenarios.

- `time.time()` returns seconds since the epoch
- `time.monotonic()` for measuring elapsed time (never goes backward)
- `time.perf_counter()` for high-precision benchmarking
- `time.strftime` / `time.strptime` mirror the datetime versions

`import json`

Why imported. JSON encoding and decoding — the standard wire format for config files, API payloads, and inter-process messages.

Used in this file. `json.JSONDecodeError`, `json.dump`, `json.dumps`, `json.load`, `json.loads`

Example. `json.loads(response.text)` # parse a JSON string to dict

Other common scenarios.

- `json.dumps(obj, indent=2)` for pretty-printing
- `json.dump(obj, file)` / `json.load(file)` for file I/O
- `default=str` handles non-serialisable types like datetime
- `object_hook=` customises decoding (e.g., to dataclass instances)

`import os`

Why imported. Operating-system interface. Path manipulation, environment variables, working-directory operations, exit codes, and thin wrappers around POSIX/Windows syscalls.

Used in this file. `os.environ`, `os.environ.get`, `os.path`, `os.path.abspath`, `os.path.dirname`, `os.path.isfile`, `os.path.join`

Example. `os.path.join(root, 'subdir', 'file.txt')` # joins with the OS-correct separator

Other common scenarios.

- `os.environ.get('API_KEY')` to read environment variables
- `os.makedirs(path, exist_ok=True)` to create nested directories
- `os.listdir(path)` to list a directory's contents
- `os.remove(path)` / `os.rename(src, dst)` to delete or move a file
- `os.getcwd()` / `os.chdir(path)` to inspect or change the working dir

```
from datetime import datetime
```

Why imported. Dates, times, durations. The fundamental temporal types: date, time, datetime, timedelta, timezone.

Used in this file. datetime

Example. datetime.now() - timedelta(days=7) # one week ago

Other common scenarios.

- datetime.strptime(s, '%Y-%m-%d') parses a string
- datetime.strftime(fmt) formats one
- datetime.fromtimestamp(n) converts a Unix epoch
- datetime.utcnow() for UTC (better: datetime.now(timezone.utc))

```
from urllib.request import Request
from urllib.request import urlopen
```

Why imported. Stdlib URL utilities — parsing, encoding, and a basic HTTP client. Mostly useful for the parsing helpers; for outbound HTTP, requests is more pleasant.

Used in this file. Request, urlopen

Example. urllib.parse.urlencode({'q': 'hello world'})

Other common scenarios.

- urllib.parse.urlparse(url) splits scheme/host/path/query
- urllib.parse.quote(s) percent-encodes a path segment
- urllib.request.urlopen(url) is the basic HTTP client

```
from urllib.error import URLError
```

Why imported. Stdlib URL utilities — parsing, encoding, and a basic HTTP client. Mostly useful for the parsing helpers; for outbound HTTP, requests is more pleasant.

Used in this file. URLError

Example. urllib.parse.urlencode({'q': 'hello world'})

Other common scenarios.

- urllib.parse.urlparse(url) splits scheme/host/path/query
- urllib.parse.quote(s) percent-encodes a path segment
- urllib.request.urlopen(url) is the basic HTTP client

```
import logging
```

Why imported. Structured, levelled logging. Replaces print() with filterable, formattable output that can route to files, stderr, syslog, or HTTP endpoints.

Used in this file. logging.error, logging.info, logging.warning

Example. logging.getLogger(__name__).info('connected to %s', host)

Other common scenarios.

- `.debug()` / `.info()` / `.warning()` / `.error()` / `.exception()`
- `logger.exception()` captures the current traceback automatically
- `logging.basicConfig(level=logging.INFO)` for quick setup
- Handlers and Formatters route logs to files / streams / syslog

```
from dashboard.database import get_all_clients
```

Why imported. Internal package — the Flask dashboard. See chapter on dashboard/.

Used in this file. `get_all_clients`

```
from dashboard.watermark_service import save_daily_profit
```

Why imported. Internal package — the Flask dashboard. See chapter on dashboard/.

Used in this file. `save_daily_profit`

Module constants

Each line below is followed by a plain-English note explaining what it does and why it is written that way.

```
_SCHEDULER_STATE_FILE = os.path.join(os.path.dirname(os.path.abspath(__file__)), '.scheduler_state.json')
```

Filesystem path resolved relative to the source file at import time — portable across machines.

Functions

```
def _load_ran_today()
```

Load the ran-today state from disk (survives module reloads).

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def _load_ran_today():
    """Load the ran-today state from disk (survives module reloads)."""
    try:
        with open(_SCHEDULER_STATE_FILE, 'r') as f:
            return json.load(f)
    except (FileNotFoundError, json.JSONDecodeError, OSError):
        return {}
```

```
def _mark_ran(job_name, date_str)
```

Mark a job as completed for a given date and persist to disk.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `state = _load_ran_today()`.
2. Assigns `state[job_name] = date_str`.
3. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def _mark_ran(job_name, date_str):
    """Mark a job as completed for a given date and persist to disk."""
    state = _load_ran_today()
    state[job_name] = date_str
    try:
        with open(_SCHEDULER_STATE_FILE, 'w') as f:
            json.dump(state, f)
    except OSError as e:
        logging.warning(f"Could not persist scheduler state: {e}")

def run_scheduler()
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Calls `logging.info(...)` for its side effect.
2. **while** `not stop_event.is_set()`: loops until the condition is false.

Code (copy-paste safe)

```
def run_scheduler():
    logging.info("Starting Daily Scheduler (watermark + quality scan + Slack)...")
    while not stop_event.is_set():
        try:
            now = datetime.utcnow()
            today = now.strftime('%Y-%m-%d')
            ran = _load_ran_today()

            # All times in UTC (datetime.utcnow)
```

```

# PythonAnywhere runs UTC natively.
# Local dev machines may be in any timezone – utcnow() ensures consistency.

# 21:00 UTC (00:00 EAT) – Midnight watermark snapshot
if now.hour == 21 and now.minute == 0 and ran.get('watermark') != today:
    logging.info("Running midnight watermark update (00:00 EAT)...")
    update_all_clients_watermarks()
    _mark_ran('watermark', today)
    time.sleep(60)

# 23:27 UTC (02:27 EAT) – Automated quality scan [TEMP TEST]
if now.hour == 23 and now.minute == 27 and ran.get('quality_scan') != today:
    logging.info("Running scheduled quality scan (TEST 02:27 EAT)...")
    run_scheduled_quality_scan()
    _mark_ran('quality_scan', today)
    time.sleep(60)

# 23:30 UTC (02:30 EAT) – Post daily summary to Slack [TEMP TEST]
if now.hour == 23 and now.minute == 30 and ran.get('slack_summary') != today:
    logging.info("Posting daily quality summary to Slack (TEST 02:30 EAT)...")
    post_slack_summary()
    _mark_ran('slack_summary', today)
    time.sleep(60)

# 23:15 UTC (02:15 EAT) – Daily database cleanup
if now.hour == 23 and now.minute == 15 and ran.get('db_cleanup') != today:
    logging.info("Running daily database cleanup (02:15 EAT)...")
    run_database_cleanup()
    _mark_ran('db_cleanup', today)
    time.sleep(60)

time.sleep(30) # Check every 30s

except Exception as e:
    logging.error(f"Scheduler error: {e}")
    time.sleep(60)

def run_scheduled_quality_scan()

```

Run the quality scan and save results — same as the API but without Flask context.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def run_scheduled_quality_scan():
    """Run the quality scan and save results – same as the API but without Flask context."""
    try:
        from dashboard.app import run_quality_scan
        from dashboard.database import save_quality_scan_results, log_action

        results = run_quality_scan()
        scan_date = datetime.now().strftime('%Y-%m-%d')
        save_quality_scan_results(scan_date, results)

        total_issues = sum(r['total_issues'] for r in results)
        log_action('QUALITY_SCAN', 'system', 'scheduler',
                  '127.0.0.1', f"Scheduled scan: {len(results)} clients, {total_issues} issues")
        logging.info(f"Quality scan complete: {len(results)} clients, {total_issues} issues")
    except Exception as e:
        logging.error(f"Scheduled quality scan failed: {e}")

def _get_slack_webhook_url()
```

Read Slack webhook URL from database, then environment, then .env file.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. **try** block with 1 **except** clause.
2. Assigns `url = os.environ.get('SLACK_WEBHOOK_URL', '').strip()`.
3. **if** `url`: branches conditionally.
4. Assigns `env_path = os.path.join(os.path.dirname(os.path.dirname(os.path.abspath(...`
5. **if** `os.path.isfile(env_path)`: branches conditionally.
6. **return** `"`.

Code (copy-paste safe)

```
def _get_slack_webhook_url():
    """Read Slack webhook URL from database, then environment, then .env file."""
    # 1. Check database (set via super admin UI)
    try:
        from dashboard.database import get_setting
        db_url = get_setting('slack_webhook_url')
        if db_url:
            return db_url
    except Exception:
        pass
    # 2. Check environment variable
    url = os.environ.get('SLACK_WEBHOOK_URL', '').strip()
    if url:
        return url
    # 3. Fallback: read from .env file in project root
```

```

env_path = os.path.join(os.path.dirname(os.path.dirname(os.path.abspath(__file__))), '.env')
if os.path.isfile(env_path):
    with open(env_path, 'r') as f:
        for line in f:
            line = line.strip()
            if line.startswith('SLACK_WEBHOOK_URL=') and not line.startswith('#'):
                return line.split('=', 1)[1].strip().strip('').strip('')
return ''

```

```
def send_slack_message(text)
```

Post a message to the configured Slack webhook.

Step by step (top-level body)

1. Assigns `webhook_url = _get_slack_webhook_url()`.
2. **if** not `webhook_url`: branches conditionally.
3. **return** `send_slack_to_webhook(webhook_url, text)`.

Code (copy-paste safe)

```

def send_slack_message(text):
    """Post a message to the configured Slack webhook."""
    webhook_url = _get_slack_webhook_url()
    if not webhook_url:
        logging.warning("Slack webhook URL not configured – skipping Slack post.")
        return False
    return send_slack_to_webhook(webhook_url, text)

```

```
def send_slack_to_webhook(webhook_url, text)
```

Post a message to a specific Slack webhook URL.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 2 **except** clauses.

Code (copy-paste safe)

```

def send_slack_to_webhook(webhook_url, text):
    """Post a message to a specific Slack webhook URL."""
    try:
        payload = json.dumps({'text': text}).encode('utf-8')
        req = Request(webhook_url, data=payload, headers={'Content-Type': 'application/json'})
        resp = urlopen(req, timeout=15)
        if resp.status == 200:
            logging.info("Slack message posted successfully.")
            return True
        else:

```

```

        logging.warning(f"Slack returned status {resp.status}")
        return False
    except URLError as e:
        logging.error(f"Slack post failed: {e}")
        return False
    except Exception as e:
        logging.error(f"Slack post error: {e}")
        return False

```

```
def _build_daily_summary_text()
```

Build the daily quality summary text (same logic as the API endpoint).

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **dict comprehension** — Builds a dict in one expression (`{k: v for k, v in items}`) — same intent as a list comprehension but for mappings.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Lazy import from dashboard.database.
2. Lazy import from config.hierarchy.
3. Lazy import from config.hierarchy.
4. Assigns `now = datetime.now()`.
5. Assigns `date = now.strftime('%Y-%m-%d')`.
6. Assigns `weekday = now.strftime('%A')`.
7. Assigns `scan_results = get_quality_scan_results(date)`.
8. Assigns `checklists = get_daily_checklists(date)`.
9. **try** block with 1 **except** clause.

10. Assigns `all_clients = hierarchy_get_all_clients()`.
11. Assigns `filtered_clients = []`.
12. `for client_name in all_clients:` iterates.
13. Assigns `total_clients = len(filtered_clients)`.
14. `if excluded_traders or excluded_clients:` branches conditionally.
15. ... and 23 more statement(s) in the body.

Code (copy-paste safe)

```
def _build_daily_summary_text():
    """Build the daily quality summary text (same logic as the API endpoint)."""
    from dashboard.database import get_quality_scan_results, get_daily_checklists
    from config.hierarchy import get_all_clients as hierarchy_get_all_clients, get_client_profile
    from config.hierarchy import SYSTEM_HIERARCHY

    # UTC date – server runs UTC so at 23:05 UTC (2:05 AM Kenyan) the date
    # is still the day we want. It flips at midnight UTC = 3 AM Kenyan.
    now = datetime.now()
    date = now.strftime('%Y-%m-%d')
    weekday = now.strftime('%A')

    scan_results = get_quality_scan_results(date)
    checklists = get_daily_checklists(date)

```

```
def post_slack_summary()
```

Build and post the daily quality summary to Slack.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

def post_slack_summary():
    """Build and post the daily quality summary to Slack."""
    try:
        text = _build_daily_summary_text()
        send_slack_message(text)
    except Exception as e:
        logging.error(f"Failed to build/post Slack summary: {e}")

```

```
def run_database_cleanup()
```

Run daily database cleanup: prune data_history, audit_log, expired sessions.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def run_database_cleanup():
    """Run daily database cleanup: prune data_history, audit_log, expired sessions."""
    try:
        from dashboard.database import cleanup_database
        results = cleanup_database()
        logging.info(f"Database cleanup results: {results}")
    except Exception as e:
        logging.error(f"Database cleanup failed: {e}")
```

```
def update_all_clients_watermarks()
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def update_all_clients_watermarks():
    try:
        clients = get_all_clients() # Returns a dict: {client_id: client_data}
        today_str = datetime.now().strftime('%Y-%m-%d')

        for client_id, client in clients.items():
            try:
                # Pull net profit directly from stored statistics
                # (already includes discrepancy from the last data push)
                stored_stats = client.get('statistics', {})
                if not isinstance(stored_stats, dict):
                    logging.info(f"Skipping {client_id}: no statistics data")
```

```

        continue

    net_profit = stored_stats.get('cashflow_inprogress', {}).get('net_profit')
    if net_profit is None:
        net_profit = stored_stats.get('profitability_completed', {}).get('net_profit')
    if net_profit is None:
        logging.info(f"Skipping {client_id}: no net_profit in statistics")
        continue

    # Save daily snapshot
    save_daily_profit(client_id, net_profit, today_str, source='auto')
    logging.info(f"Updated watermark for {client_id}: {net_profit}")

except Exception as e:
    logging.error(f"Error updating client {client_id}: {e}")

except Exception as e:
    logging.error(f"Error in update_all_clients_watermarks: {e}")

def start_scheduler()

```

Why these Python concepts were used

- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **global** — Rebinds a module-level name from inside the function. A smell in larger codebases — usually means a singleton or cache that could be passed in instead.

Step by step (top-level body)

1. Declares globals: `_scheduler_started`.
2. `if os.environ.get('WERKZEUG_RUN_MAIN') == 'false':` branches conditionally.
3. `with _scheduler_lock:` enters a context manager.
4. Calls `stop_event.clear(...)` for its side effect.
5. Assigns `t = threading.Thread(target=run_scheduler, daemon=True)`.
6. Calls `t.start(...)` for its side effect.
7. `return t`.

Code (copy-paste safe)

```

def start_scheduler():
    global _scheduler_started
    # Flask's Werkzeug reloader spawns TWO processes: a parent watcher and a
    # child that actually serves. Only start the scheduler in the child
    # (WERKZEUG_RUN_MAIN='true') to avoid duplicate threads. When the
    # reloader is disabled (e.g. production), WERKZEUG_RUN_MAIN is unset and
    # there is only one process – that's fine, start normally.
    if os.environ.get('WERKZEUG_RUN_MAIN') == 'false':
        return None # Parent watcher process – skip
    with _scheduler_lock:
        if _scheduler_started:
            logging.info("Scheduler already running – skipping duplicate start.")
            return None
        _scheduler_started = True

```

```
# Ensure stop_event is clear so the new thread's loop runs
stop_event.clear()
t = threading.Thread(target=run_scheduler, daemon=True)
t.start()
return t
```

Step 11.12 — Build dashboard/app.py

What to do. Create the file dashboard/app.py in your project root and paste in the code shown in this step. The file is **10470** lines long; we walk through it piece by piece below.

Depends on. This file imports from internal modules built in earlier steps: dashboard, config. If any of those imports fail, jump back to the step that introduced them.

What this file is for. The Flask application factory. Registers blueprints, sets up session config, attaches scheduled jobs, and exposes the request-time hooks (login required, role checks).

dashboard/app.py

10470 loc · 2 classes · 172 functions · 25 imports

The Flask application factory. Registers blueprints, sets up session config, attaches scheduled jobs, and exposes the request-time hooks (login required, role checks). It defines **2** classes and **172** module-level functions, across **10,470** lines.

Python concepts demonstrated in this module

- Classes and objects
- Closures
- Comprehensions
- Context managers (with-statements)
- Decorators
- Exceptions
- Flask routes
- f-strings
- Inheritance
- Lambdas
- Type hints

Imports — what each one is for

```
from flask import Flask
from flask import render_template
from flask import jsonify
from flask import request
from flask import redirect
from flask import url_for
from flask import g
```

Why imported. Lightweight WSGI web framework. Powers the dashboard.

Used in this file. Flask, g, jsonify, redirect, render_template, request, url_for

Example. @app.route('/login', methods=['POST'])\ndef login(): ...

Other common scenarios.

- request.form / request.args / request.json read input
- render_template('x.html', **ctx) renders a Jinja2 template

- `redirect(url_for('view'))` builds URLs from view names
- Blueprints split a large app into pluggable sub-apps

```
from flask_compress import Compress
```

Why imported. *flask_compress* — module specific to this codebase. See the chapter that covers its source for the full definition.

Used in this file. *Compress*

```
from flask_limiter import Limiter
```

Why imported. Per-route rate limiting for Flask — protects login pages and ingestion endpoints from brute force / abuse.

Used in this file. *Limiter*

Example. `@limiter.limit('5/minute')\ndef login(): ...`

Other common scenarios.

- Default keying is by remote IP
- Override `key_func` to limit by user id or API key

```
from flask_limiter.util import get_remote_address
```

Why imported. Per-route rate limiting for Flask — protects login pages and ingestion endpoints from brute force / abuse.

Used in this file. *get_remote_address*

Example. `@limiter.limit('5/minute')\ndef login(): ...`

Other common scenarios.

- Default keying is by remote IP
- Override `key_func` to limit by user id or API key

```
import threading
```

Why imported. Threads and synchronisation primitives. Used when work is I/O-bound and the GIL is not a bottleneck (the GIL prevents speed-up on CPU-bound work).

Used in this file. *threading.Thread*

Example. `Thread(target=worker, args=(q,), daemon=True).start()`

Other common scenarios.

- `Lock` / `RLock` to guard shared state
- `Event` for one-shot signals between threads
- `Queue` (from `queue`) for producer/consumer patterns
- `threading.local()` for thread-local storage

```
import json
```

Why imported. JSON encoding and decoding — the standard wire format for config files, API payloads, and inter-process messages.

Used in this file. `json.dumps`, `json.loads`

Example. `json.loads(response.text)` # parse a JSON string to dict

Other common scenarios.

- `json.dumps(obj, indent=2)` for pretty-printing
- `json.dump(obj, file)` / `json.load(file)` for file I/O
- `default=str` handles non-serialisable types like `datetime`
- `object_hook=` customises decoding (e.g., to `dataclass` instances)

`import os`

Why imported. Operating-system interface. Path manipulation, environment variables, working-directory operations, exit codes, and thin wrappers around POSIX/Windows syscalls.

Used in this file. `os.getenv`, `os.path`, `os.path.abspath`, `os.path.dirname`

Example. `os.path.join(root, 'subdir', 'file.txt')` # joins with the OS-correct separator

Other common scenarios.

- `os.environ.get('API_KEY')` to read environment variables
- `os.makedirs(path, exist_ok=True)` to create nested directories
- `os.listdir(path)` to list a directory's contents
- `os.remove(path)` / `os.rename(src, dst)` to delete or move a file
- `os.getcwd()` / `os.chdir(path)` to inspect or change the working dir

`import sys`

Why imported. Access to the running interpreter — `argv`, `stdin/stdout`, exit codes, the import search path, and the platform name.

Used in this file. `sys.path`, `sys.path.append`, `sys.stderr`

Example. `sys.exit(1)` # terminate the process with a non-zero status

Other common scenarios.

- `sys.argv[1:]` reads the command-line arguments
- `sys.path.insert(0, 'extra')` prepends to the import search path
- `sys.stderr.write(msg)` writes to standard error
- `sys.platform` tells you 'win32', 'linux', or 'darwin'
- `sys.modules` is the global cache of already-imported modules

`import logging`

Why imported. Structured, levelled logging. Replaces `print()` with filterable, formattable output that can route to files, `stderr`, `syslog`, or HTTP endpoints.

Used in this file. logging.DEBUG, logging.FileHandler, logging.Formatter, logging.INFO, logging.StreamHandler, logging.WARNING, logging.basicConfig, logging.debug

Example. logging.getLogger(__name__).info('connected to %s', host)

Other common scenarios.

- .debug() / .info() / .warning() / .error() / .exception()
- logger.exception() captures the current traceback automatically
- logging.basicConfig(level=logging.INFO) for quick setup
- Handlers and Formatters route logs to files / streams / syslog

```
import time
```

Why imported. Timestamps and sleep. Lower-level than datetime — works in Unix-epoch seconds.

Used in this file. time.monotonic, time.sleep, time.time

Example. time.sleep(1.5) # pause this thread for 1.5 seconds

Other common scenarios.

- time.time() returns seconds since the epoch
- time.monotonic() for measuring elapsed time (never goes backward)
- time.perf_counter() for high-precision benchmarking
- time.strftime / time.strptime mirror the datetime versions

```
import errno
```

Why imported. *errno* — module specific to this codebase. See the chapter that covers its source for the full definition.

Used in this file. errno.EPIPE

```
import signal
```

Why imported. Receive POSIX/Windows signals — SIGINT (Ctrl-C), SIGTERM, etc. Used to install graceful-shutdown handlers.

Used in this file. signal.SIGPIPE, signal.SIG_DFL, signal.signal

Example. signal.signal(signal.SIGTERM, on_term)

Other common scenarios.

- Only the main thread can install handlers
- On Windows, SIGTERM is mostly equivalent to a force-kill

```
from functools import wraps
```

Why imported. Higher-order helpers — caching, partial application, decorator authoring tools, reducers.

Used in this file. wraps

Example. @lru_cache(maxsize=128) # memoise this pure function

Other common scenarios.

- `partial(f, x=1)` pre-binds arguments
- `reduce(f, iterable)` folds an iterable to a single value
- `@wraps(fn)` preserves `__name__`/`__doc__` when writing decorators
- `@cached_property` memoises a property per-instance

```
import secrets
```

Why imported. Cryptographically strong randomness — tokens, session IDs, API keys. Never use `random` for anything security-sensitive.

Used in this file. `secrets.token_hex`

Example. `secrets.token_urlsafe(32)` # 32-byte url-safe random string

Other common scenarios.

- `secrets.token_hex(n)` for a hex string
- `secrets.choice(seq)` is the cryptographic equivalent of `random.choice`
- `secrets.compare_digest(a, b)` for timing-safe comparison

```
import hashlib
```

Why imported. Cryptographic hash functions — SHA-256, MD5, BLAKE2.

Used in this file. *No direct attribute access detected — likely imported for side effects, re-export, or string references.*

Example. `hashlib.sha256(b'hello').hexdigest()`

Other common scenarios.

- Pass data in chunks via `.update()` to hash large files
- Use `sha256` / `sha512` for integrity; never MD5 or SHA-1 for security
- For password hashing use `bcrypt`/`argon2`, NOT raw `hashlib`

```
import re
```

Why imported. Regular expressions. Pattern matching, search, replace, and text extraction.

Used in this file. `re.IGNORECASE`, `re.compile`, `re.findall`, `re.match`, `re.search`, `re.sub`

Example. `re.search(r'\d{3}-\d{4}', text)` # returns a `Match` or `None`

Other common scenarios.

- `re.findall(pattern, text)` for every non-overlapping match
- `re.sub(pattern, repl, text)` to replace occurrences
- `re.compile(...)` to reuse a pattern (faster in a loop)
- Named groups: `r'(?P<year>\d{4})'` lets you do `m.group('year')`

```
from datetime import datetime
from datetime import timedelta
```

Why imported. Dates, times, durations. The fundamental temporal types: date, time, datetime, timedelta, timezone.

Used in this file. datetime, timedelta

Example. datetime.now() - timedelta(days=7) # one week ago

Other common scenarios.

- datetime.strptime(s, '%Y-%m-%d') parses a string
- datetime.strftime(fmt) formats one
- datetime.fromtimestamp(n) converts a Unix epoch
- datetime.utcnow() for UTC (better: datetime.now(timezone.utc))

from dashboard.database import get_all_kyc_links
from dashboard.database import is_kyc_primary
```

Why imported. Internal package — the Flask dashboard. See chapter on dashboard/.

Used in this file. `add_kyc_link`, `admin_password_exists`, `check_and_repair_database`, `compare_versions`, `copy_admin_password_row`, `create_session`, `create_user`, `deactivate_user`, `delete_client_data`, `delete_session`, `delete_user_credential`, `find_user_by_identifier` ... (+34 more)

```
from dashboard.notes_service import get_client_notes
from dashboard.notes_service import save_client_note
from dashboard.notes_service import delete_client_note
```

Why imported. Internal package — the Flask dashboard. See chapter on dashboard/.

Used in this file. `delete_client_note`, `get_client_notes`, `save_client_note`

```
from dashboard.utils.trade_matcher import UnifiedTradeMatcher
```

Why imported. Internal package — the Flask dashboard. See chapter on dashboard/.

Used in this file. *No direct attribute access detected — likely imported for side effects, re-export, or string references.*

```
from logging.handlers import RotatingFileHandler
```

Why imported. Structured, levelled logging. Replaces `print()` with filterable, formattable output that can route to files, stderr, syslog, or HTTP endpoints.

Used in this file. `RotatingFileHandler`

Example. `logging.getLogger(__name__).info('connected to %s', host)`

Other common scenarios.

- `.debug()` / `.info()` / `.warning()` / `.error()` / `.exception()`
- `logger.exception()` captures the current traceback automatically
- `logging.basicConfig(level=logging.INFO)` for quick setup
- Handlers and Formatters route logs to files / streams / syslog

```
import signal
```

Why imported. Receive POSIX/Windows signals — `SIGINT` (Ctrl-C), `SIGTERM`, etc. Used to install graceful-shutdown handlers.

Used in this file. `signal.SIGPIPE`, `signal.SIG_DFL`, `signal.signal`

Example. `signal.signal(signal.SIGTERM, on_term)`

Other common scenarios.

- Only the main thread can install handlers
- On Windows, `SIGTERM` is mostly equivalent to a force-kill

```
from dashboard.financial_overview import calculate_all_financials
```

Why imported. Internal package — the Flask dashboard. See chapter on dashboard/.

Used in this file. `calculate_all_financials`

Module constants

Each line below is followed by a plain-English note explaining what it does and why it is written that way.

```
BEF_HIDDEN_FIRMS = {'lucid', 'apex', 'tradeday', 'toponefutures'}
```

Mapping or set literal — a lookup table referenced elsewhere in the module.

```
_RECENT_LOG_PATH = 'dashboard/server_recent.log'
```

String literal — fixed at code-load time.

```
_RECENT_LOG_RE = re.compile('^\\[((?:\\d{4}-\\d{2}-\\d{2}) ?)\\d{2}:\\d{2}:\\d{2}(?:,\\d+)?\\]\\')
```

Pre-compiled regular expression — compiled once at import time and reused, which is faster than compiling on every call.

```
_LOG_LEVEL_NAME = str(os.getenv('DASHBOARD_LOG_LEVEL', 'INFO')).upper()
```

Module-level constant — bound once at import time and referenced from the functions and classes below.

```
_LOG_LEVEL = getattr(logging, _LOG_LEVEL_NAME, logging.INFO)
```

Module-level constant — bound once at import time and referenced from the functions and classes below.

```
_STATS_TAB_TTL = 300
```

Numeric literal — a tunable parameter compiled into the source.

```
DASHBOARD_OWNED_EVAL_KEYS = frozenset({'Payout 1', 'Date 1', 'Payout 2', 'Date 2', 'Payout 3', 'Date 3',  
    'Payout 4', 'Date 4', 'Payout 5', 'Date 5', 'Payout 6', 'Dat...
```

Module-level constant — bound once at import time and referenced from the functions and classes below.

```
MAINTENANCE_MODE = False
```

Module-level constant — bound once at import time and referenced from the functions and classes below.

```
MAINTENANCE_EXEMPT = {'super_admin', 'bef_admin', 'kwok_admin', 'admin', 'trader'}
```

Mapping or set literal — a lookup table referenced elsewhere in the module.

```
_INTERNAL_DEAL_TYPES_INT = {2, 3}
```

Mapping or set literal — a lookup table referenced elsewhere in the module.

```
_INTERNAL_DEAL_TYPES_STR = {'BALANCE', '2', '2.0', 'CREDIT', '3', '3.0', 'DEAL_TYPE_BALANCE',  
    'DEAL_TYPE_CREDIT'}
```

Mapping or set literal — a lookup table referenced elsewhere in the module.

Classes

```
class UnbufferedFileHandler(logging.FileHandler)
```

Code (copy-paste safe)

```
class UnbufferedFileHandler(logging.FileHandler):
    def emit(self, record):
        super().emit(record)
        self.stream.flush()
```

Method: UnbufferedFileHandler.emit

```
def emit(self, record)
```

Step by step (top-level body)

1. Calls `super().emit(...)` for its side effect.
2. Calls `self.stream.flush(...)` for its side effect.

Code (copy-paste safe)

```
def emit(self, record):
    super().emit(record)
    self.stream.flush()
```

```
class TraderStyleFormatter(logging.Formatter)
```

Compact log format to match Trader Companion readability.

Code (copy-paste safe)

```
class TraderStyleFormatter(logging.Formatter):
    """Compact log format to match Trader Companion readability."""

    def format(self, record):
        stamp = datetime.fromtimestamp(record.created).strftime('%H:%M:%S')
        msg = record.getMessage()
        if record.levelno >= logging.WARNING:
            msg = f"[{record.levelname}] {msg}"
        return f"[{stamp}] {msg}"
```

Method: TraderStyleFormatter.format

```
def format(self, record)
```

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `stamp = datetime.fromtimestamp(record.created).strftime('%H:%M:%S')`.
2. Assigns `msg = record.getMessage()`.
3. **if** `record.levelno >= logging.WARNING`: branches conditionally.
4. **return** `f"[{stamp}] {msg}"`.

Code (copy-paste safe)

```
def format(self, record):
    stamp = datetime.fromtimestamp(record.created).strftime('%H:%M:%S')
    msg = record.getMessage()
```

```

if record.levelno >= logging.WARNING:
    msg = f"[{record.levelname}] {msg}"
    return f"[{stamp}] {msg}"

```

Functions

```
def _parse_recent_log_timestamp(ts_text)
```

Parse either full datetime or time-only log stamps.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

Step by step (top-level body)

1. **for** `fmt` in `('%Y-%m-%d %H:%M:%S,%f', '%Y-%m-%d %H:%M:%S')`: iterates.
2. **for** `fmt` in `('%H:%M:%S,%f', '%H:%M:%S')`: iterates.
3. **return** `None`.

Code (copy-paste safe)

```

def _parse_recent_log_timestamp(ts_text):
    """Parse either full datetime or time-only log stamps."""
    # Full timestamp variants.
    for fmt in ('%Y-%m-%d %H:%M:%S,%f', '%Y-%m-%d %H:%M:%S'):
        try:
            return datetime.strptime(ts_text, fmt)
        except ValueError:
            pass

    # Time-only variants (new concise format): assume today, with a safe
    # midnight rollover fallback when a future time appears.
    for fmt in ('%H:%M:%S,%f', '%H:%M:%S'):
        try:
            t = datetime.strptime(ts_text, fmt).time()
            now = datetime.now()
            parsed = datetime.combine(now.date(), t)
            if parsed - now > timedelta(minutes=5):
                parsed -= timedelta(days=1)
            return parsed
        except ValueError:
            pass
    return None

```

```
def _purge_recent_log(log_path=_RECENT_LOG_PATH, hours=1)
```

Trim log_path in-place, keeping only entries from the last `hours` hours.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def _purge_recent_log(log_path=_RECENT_LOG_PATH, hours=1):
    """Trim log_path in-place, keeping only entries from the last `hours` hours."""
    try:
        cutoff = datetime.now() - timedelta(hours=hours)
        with open(log_path, 'r', encoding='utf-8', errors='replace') as fh:
            lines = fh.readlines()
            kept = []
            for line in lines:
                m = _RECENT_LOG_RE.match(line)
                if m:
                    ts = _parse_recent_log_timestamp(m.group(1))
                    if ts is None:
                        kept.append(line) # unparseable timestamp → keep
                    elif ts >= cutoff:
                        kept.append(line)
                    # else: drop – older than the window
                else:
                    # Continuation / blank lines: keep only if we have recent content
                    if kept:
                        kept.append(line)
            with open(log_path, 'w', encoding='utf-8') as fh:
                fh.writelines(kept)
    except (FileNotFoundError, IOError):
        pass
```

```
def _start_recent_log_purger(log_path=_RECENT_LOG_PATH, interval_minutes=5)
```

Daemon thread: prune entries older than 1 hour from the recent log every 5 minutes.

Why these Python concepts were used

- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.

Step by step (top-level body)

1. Defines a nested function `_worker(...)`.
2. Assigns `t = threading.Thread(target=_worker, daemon=True, name='recen...`
3. Calls `t.start(...)` for its side effect.

Code (copy-paste safe)

```
def _start_recent_log_purger(log_path=_RECENT_LOG_PATH, interval_minutes=5):
    """Daemon thread: prune entries older than 1 hour from the recent log every 5 minutes."""
    def _worker():
        while True:
            time.sleep(interval_minutes * 60)
            _purge_recent_log(log_path)
    t = threading.Thread(target=_worker, daemon=True, name='recent-log-purger')
    t.start()
```

```
@app.before_request
def _log_request_start()
```

Why these Python concepts were used

- **@app.before_request** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.

Step by step (top-level body)

1. Assigns `g._request_start = time.monotonic()`.

Code (copy-paste safe)

```
def _log_request_start():
    g._request_start = time.monotonic()
```

```
@app.before_request
def _decompress_request_body()
```

Why these Python concepts were used

- **@app.before_request** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. `if request.headers.get('Content-Encoding') == 'gzip':` branches conditionally.

Code (copy-paste safe)

```
def _decompress_request_body():
    if request.headers.get('Content-Encoding') == 'gzip':
        import gzip as _gzip
        import io as _io
        try:
            # Read directly from wsgi.input BEFORE Werkzeug wraps it into a
            # LimitedStream or caches it – calling request.get_data() here would
            # cache the compressed bytes and the JSON parser would see garbage.
            raw_stream = request.environ.get('wsgi.input')
            content_length = request.environ.get('CONTENT_LENGTH')
            try:
                compressed_size = int(content_length) if content_length else 0
            except (TypeError, ValueError):
                compressed_size = 0

            if raw_stream and compressed_size > 0:
                compressed = raw_stream.read(compressed_size)
```

```

    else:
        compressed = raw_stream.read() if raw_stream else b''
        decompressed = _gzip.decompress(compressed)
        request.environ['wsgi.input'] = _io.BytesIO(decompressed)
        request.environ['CONTENT_LENGTH'] = str(len(decompressed))
        request.environ.pop('HTTP_CONTENT_ENCODING', None)
except Exception as e:
    logging.warning(f'[DECOMPRESS] Failed to decompress gzip request: {e}')

```

```

@app.after_request
def _log_request_end(response)

```

Why these Python concepts were used

- **@app.after_request** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **raise** — Raises an exception explicitly. Either signals an invalid argument the caller should fix, or re-raises after logging.

Step by step (top-level body)

1. **try** block with 1 **except** clause.
2. **return** response.

Code (copy-paste safe)

```

def _log_request_end(response):
    try:
        duration_ms = (time.monotonic() - getattr(g, '_request_start', time.monotonic())) * 1000
        logging.info('[REQ] %s %s -> %s (%.1fms)', request.method, request.path, response.status_code,
                     duration_ms)
    except OSError as e:
        # Client disconnected during response write (SIGPIPE / broken pipe)
        # This is benign and not a server error – suppress as debug log
        if e.errno == errno.EPIPE:
            logging.debug('[REQ_BROKEN_PIPE] Client disconnect on %s %s', request.method, request.path)
        else:
            raise
    return response

```

```

def _init_database_pool()

```

Initialize database connection pool on app startup.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

- **raise** — Raises an exception explicitly. Either signals an invalid argument the caller should fix, or re-raises after logging.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def _init_database_pool():
    """Initialize database connection pool on app startup."""
    try:
        from dashboard.database import _init_pool
        _init_pool()
        logging.info("[STARTUP] Database connection pool initialized")
    except Exception as e:
        logging.error(f"[STARTUP ERROR] Failed to initialize DB pool: {e}")
        raise
```

```
def get_account_signature(account_number)
```

*Extract account signature for matching: first 4 + last 4/5 digits. This handles truncated account numbers in MT5 comments. Handles truncated format with '...' like: FNFT...59574 Examples:
MFFUEVSTP326057008 -> mffu7008 (full account) FNFT...59574 -> fnft59574 (truncated - keep last 5)
12345678 -> 12345678*

Why these Python concepts were used

- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **if not account_number**: branches conditionally.
2. Assigns `account_str = str(account_number).strip()`.
3. **if '...' in account_str**: branches conditionally.
4. **if len(account_str) < 8**: branches conditionally.
5. **return** (`account_str[:4] + account_str[-4:].lower()`).

Code (copy-paste safe)

```
def get_account_signature(account_number):
    """
    Extract account signature for matching: first 4 + last 4/5 digits.
    This handles truncated account numbers in MT5 comments.

    Handles truncated format with '...' like: FNFT...59574

    Examples:
    MFFUEVSTP326057008 -> mffu7008 (full account)
    FNFT...59574 -> fnft59574 (truncated - keep last 5)
    12345678 -> 12345678
    """
    if not account_number:
        return None

    account_str = str(account_number).strip()
```

```

# Handle truncated format: PREFIX...SUFFIX
if '...' in account_str:
    parts = account_str.split('...')
    if len(parts) == 2:
        prefix = parts[0][:4] if len(parts[0]) >= 4 else parts[0]
        suffix = parts[1] # Keep full suffix (usually 5 digits)
        return (prefix + suffix).lower()

# Standard format: first 4 + last 4
if len(account_str) < 8:
    return account_str.lower()

# First 4 + last 4
return (account_str[:4] + account_str[-4:]).lower()

```

```
def get_last_n_digits(account: str, n: int=5) -> str
```

Extract last N digits from account number. Prioritizes digits at the end of the string to avoid prefix contamination.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `account: str, n: int`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> str`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to `sum`, `any`, `all`, or `max` where the intermediate list would be wasted.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Imports `re` (lazy import inside the function).
2. `if not account:` branches conditionally.
3. Assigns `match = re.search('(\d+)$', str(account).strip())`.
4. `if match:` branches conditionally.
5. Assigns `digits = "".join((c for c in str(account) if c.isdigit()))`.
6. `return digits[-n:] if len(digits) >= n else digits`.

Code (copy-paste safe)

```

def get_last_n_digits(account: str, n: int = 5) -> str:
    """
    Extract last N digits from account number.
    Prioritizes digits at the end of the string to avoid prefix contamination.
    """
    import re
    if not account:

```

```

# Try to extract the final sequence of digits
match = re.search(r'(\d+)$', str(account).strip())
if match:
    digits = match.group(1)
    # For Topstep (V2-) or short accounts, ensure we don't demand more digits than exist
    if len(digits) < n:
        return digits
    return digits[-n:]

# Fallback: extract all digits
digits = ''.join(c for c in str(account) if c.isdigit())
return digits[-n:] if len(digits) >= n else digits

def match_account_to_evaluation(account_number, evaluations, phase_code)

```

Find ALL matching evaluations for an account number based on phase. For Challenge (CH): Match against 'Account #' column For Funded/DoubleDip (FD, DD): Match against 'Account #.1' column For Farming (FA): Match against 'Account #.1' (funded); if blank, fall back to 'Account #' (challenge) Returns: List of (eval_index, matched_account)

Why these Python concepts were used

- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.

Step by step (top-level body)

1. Imports logging (lazy import inside the function).
2. Assigns matches = [].
3. **if** not account_number: branches conditionally.
4. Assigns target_sig = get_account_signature(account_number).
5. Assigns target_last5 = get_last_n_digits(account_number, 5).
6. Calls logging.debug(...) for its side effect.
7. **if** not target_sig and (not target_last5): branches conditionally.
8. Defines a nested function get_prefix(...).
9. Assigns target_prefix = get_prefix(account_number).
10. Assigns _PLACEHOLDER_ACCOUNTS = {'', 'none', '-', '—', '—', 'n/a', 'na', 'tbd', 'pending'}.
11. Defines a nested function _is_real_account(...).
12. Assigns combined_accounts = [].
13. **for** (idx, ev) in enumerate(evaluations): iterates.
14. Assigns is_topstep = str(account_number).upper().startswith('V2').

15. ... and 4 more statement(s) in the body.

Code (copy-paste safe)

```

```

```
def parse_sheet_date(date_str)
```

Parse date string from Google Sheet into datetime object. Supports formats: DD/MM/YYYY, YYYY-MM-DD, MM/DD/YYYY, etc.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

Step by step (top-level body)

1. **if not date_str**: branches conditionally.
2. Assigns `date_str = str(date_str).strip()`.
3. **if not date_str**: branches conditionally.
4. Assigns `formats = ['%m/%d/%Y', '%d/%m/%Y', '%Y-%m-%d', '%m/%d/%y', '%d/%m/%....`
5. **for** `fmt` in `formats`: iterates.
6. **return** `None`.

Code (copy-paste safe)

```

def parse_sheet_date(date_str):
    """
    Parse date string from Google Sheet into datetime object.
    Supports formats: DD/MM/YYYY, YYYY-MM-DD, MM/DD/YYYY, etc.
    """
    if not date_str:
        return None

    date_str = str(date_str).strip()
    if not date_str:
        return None

```

```

formats = [
    '%m/%d/%Y', '%d/%m/%Y', '%Y-%m-%d',
    '%m/%d/%y', '%d/%m/%y',
    '%d-%m-%Y', '%Y/%m/%d', '%d.%m.%Y'
]

for fmt in formats:
    try:
        val = datetime.strptime(date_str, fmt)
        # FORCE TO UTC or STRIP TIMEZONE?
        # MT5 timestamps are usually UTC or server time (which we convert to timestamps).
        # If sheet dates are parsed as naive 00:00:00, and we compare to
        # trade times which might be later in the day, that's fine.
        # But if a trade happens at 23:00 on Feb 18 (UTC), and sheet says Feb 18...
        # The trade timestamp (TS) > Date Purchased TS.
        # But if timezone is involved, eg. Sheet date is parsed as local time?
        # datetime.strptime creates NAIVE datetime.

        # If there's a 1-day difference being observed, it's likely a timezone shift display issue?
        # Or the dashboard is displaying dates differently?
        # Or maybe pandas parsing?

        # User says: "one day difference between the dates on the sheets and the dates on the dashboard"
        # If Sheet says Feb 18, Dashboard says Feb 17? Or Feb 19?

        # If date_str is "2/18/26", datetime is 2026-02-18 00:00:00

        # FIX: Use simple parsing - keep naive dates as imported
        # If date_str is "2/18/26", datetime is 2026-02-18 00:00:00

        return val
    except ValueError:
        continue

return None

```

```
def filter_matches_by_date(matches, evaluations, trade_timestamp, phase_code=None, trade_number=None)
```

Filter matches to find the best matching evaluation. Universal logic for ALL prop firms: - When multiple rows match the same account, always prefer the LATEST row (highest eval_index = most recently added to the dashboard). - Date filtering is used as a secondary signal but never overrides the "latest row wins" rule. Args: matches: List of (eval_index, matched_account) evaluations: List of evaluation dicts trade_timestamp: Timestamp of the trade (float or int) phase_code: (Optional) Phase code to help determine target field for placeholder check trade_number: (Optional) Trade number for target field check

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression ([f(x) for x in xs]). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.

Step by step (top-level body)

1. **if** not matches: branches conditionally.
2. **if** not trade_timestamp: branches conditionally.
3. **try** block with 1 **except** clause.
4. Assigns valid_matches = [].
5. Assigns BUFFER_SECONDS = 2 * 24 * 3600.
6. **for** (eval_idx, matched_acc) in matches: iterates.

    return evaluations
```

```
def _evaluation_row_merge_key(ev)
```

Stable identity for matching a pushed row to the same row in the DB. Index-based merge breaks when row order changes, when only a subset of rows is pushed (active trades / billing), or when new rows are inserted — which caused Activation Fee and other dashboard-owned fields to attach to the wrong evaluation or appear to "not persist".

Why these Python concepts were used

- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.

Step by step (top-level body)

1. **if** not isinstance(ev, dict): branches conditionally.
2. Assigns firm = (ev.get('Prop Firm') or "").strip().lower().replace(' ', ...)
3. Assigns a0 = (ev.get('Account #') or "").strip().lower().
4. Assigns a1 = (ev.get('Account #.1') or "").strip().lower().
5. Assigns sz = (ev.get('Account Size') or "").strip().lower().
6. Assigns accts = tuple(sorted((a for a in (a0, a1) if a))).
7. **if** not firm and (not accts): branches conditionally.
8. **return** (firm, accts, sz).

Code (copy-paste safe)

```
def _evaluation_row_merge_key(ev):
    """Stable identity for matching a pushed row to the same row in the DB.

    Index-based merge breaks when row order changes, when only a subset of rows
```

```

return (firm, accts, sz)

```

```
def _apply_dashboard_owned_merge(merged, base_row, incoming_row, force_fields)
```

Preserve dashboard-owned fields from base_row onto merged (mutates merged).

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

Step by step (top-level body)

1. **for** key in DASHBOARD_OWNED_EVAL_KEYS: iterates.

Code (copy-paste safe)

```

def _apply_dashboard_owned_merge(merged, base_row, incoming_row, force_fields):
    """Preserve dashboard-owned fields from base_row onto merged (mutates merged)."""
    for key in DASHBOARD_OWNED_EVAL_KEYS:
        if key in force_fields:
            if key in incoming_row:
                merged[key] = incoming_row[key]
            continue
        existing_val = base_row.get(key)
        if existing_val and str(existing_val).strip() not in ('', '-'):
            if key in ('Fee', 'Activation Fee'):
                try:
                    numeric = float(str(existing_val).replace('$', '').replace(',', '').strip())
                    if numeric == 0:
                        continue
                except (ValueError, TypeError):
                    pass
            merged[key] = existing_val

```

```
def merge_evaluation_push_with_existing(existing_evals, incoming_evals, force_fields=None)
```

Merge incoming evaluation rows into the full stored list by row identity. - Patches rows that match (firm + account numbers + size); never drops existing rows when the push only contains a subset (e.g. active trades). - Appends rows that have no match (new accounts from the sheet/trader).

Why these Python concepts were used

- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **if** not incoming_evals: branches conditionally.
2. Assigns force_fields = set(force_fields or []).
3. Assigns existing_evals = existing_evals or [].
4. Assigns incoming_evals = incoming_evals or [].
5. Assigns key_to_idx = {}.
6. **for** (i, ex) in enumerate(existing_evals): iterates.
7. Assigns out = [].
8. **for** ex in existing_evals: iterates.
9. Assigns appended = [].
10. **for** (i, ev_in) in enumerate(incoming_evals): iterates.
11. Calls out.extend(...) for its side effect.
12. **return** out.

Code (copy-paste safe)

```
def merge_evaluation_push_with_existing(existing_evals, incoming_evals, force_fields=None):
    """Merge incoming evaluation rows into the full stored list by row identity.

    - Patches rows that match (firm + account numbers + size); never drops
      existing rows when the push only contains a subset (e.g. active trades).
    - Appends rows that have no match (new accounts from the sheet/trader).
    """
    if not incoming_evals:
        return list(existing_evals) if existing_evals else []

    force_fields = set(force_fields or [])

out.extend(appended)
return out

```

```
def recalculate_hedge_nets(evaluations)
```

Recalculate Hedge Net and Hedge Net.1 for every evaluation row. Uses the same formulas as the Google Sheet import in data_processor.py so that values stay correct whenever hedge results or statuses change.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.

Step by step (top-level body)

1. Defines a nested function `_num(...)`.
2. Defines a nested function `_is_blank(...)`.
3. **for** `ev` in `evaluations` or `[]`: iterates.
4. **return** `evaluations`.

Code (copy-paste safe)

```

def recalculate_hedge_nets(evaluations):
    """Recalculate Hedge Net and Hedge Net.1 for every evaluation row.

    Uses the same formulas as the Google Sheet import in data_processor.py
    so that values stay correct whenever hedge results or statuses change.
    """

```

```

def update_evaluations_from_aggregated_data(evaluations, aggregated_data=None, raw_deals=None,
    tradovate_farming_days=None)

```

Update evaluation hedge result fields from aggregated MT5 comment data OR raw deals. If 'raw_deals' is provided, performs server-side aggregation (Session Matching). Otherwise, uses client-provided 'aggregated_data'. Args: evaluations: List of evaluation records aggregated_data: List of aggregated trade data (from client) raw_deals: List of raw MT5 deal objects (from client) tradovate_farming_days: List of Tradovate MNQ daily P&L per account (for Prop Day values) Returns: Tuple of (updated_evaluations, match_log)

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression ([f(x) for x in xs]). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **set comprehension** — Builds a set in one expression — usually to deduplicate the result of a transform.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

# Update Logic: ACCUMULATE profit for this push
# Since we are processing all history in this push, we should sum up sessions for the same eval
# But be careful not to sum with existing OLD values from DB if we are replacing them?
# Actually, update_evaluations... is called on the existing 'evaluations' list from DB.
# If we just add, we might double count if we run this multiple times?
# No, 'evaluations' object is transient for this request (loaded from DB/Sheet).
# The 'session_profit' is from the NEW deals being pushed.
# Users usually push ALL history.
# So we should probably clear the field first if it's the first time we touch it IN THIS REQUEST
# Or just assume we are recalculating from scratch for these deals.

# For robustness: valid numeric check (handle $ formatting)

# SPECIAL CASE: FundedNext (or others) where multiple evals share account?
# The user said: "one account number belongs to several prop firm evaluations, this only happens once"
# "The rest should just push directly"
# If we touch the same field multiple times in this loop (multiple sessions for same eval), we should sum them
# If the eval field already has value from previous pushes (DB), and we are pushing partial calculation, we should add
# Usually pushes contain full history.
# Let's assume we accumulate.

# However, if this is the FIRST time we are updating this specific field IN THIS BATCH,
# and we want to overwrite old DB data with new calculation?
# The 'evaluations' list comes from DB.
# If we want to replace the old 'Hedge Result' with the new value from this push,
# We should probably track which fields we've updated.

# Key to track uniqueness: (Eval Index, Field Name)
update_key = (candidates.index(best_eval) if best_eval in candidates else -1, field_name)

        print("kwok_admin password initialized or migrated from legacy showcase_admin row")

def provision_hierarchy_passwords()
```

Auto-create or reset user_credentials with default password for hierarchy users.

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.
- **nonlocal** — Declares a name as belonging to an enclosing function's scope. The flag that says *this nested function is rebinding the outer variable, not creating its own*.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns default_pw = 'Test@123'.
2. Assigns created = 0.
3. Assigns reset = 0.

4. Defines a nested function `ensure_password(...)`.
5. `for (admin_name, admin_data) in hierarchy.get('admins', {}).items():` iterates.
6. `if created or reset:` branches conditionally.

Code (copy-paste safe)

```
def provision_hierarchy_passwords():
    """Auto-create or reset user_credentials with default password for hierarchy users."""
    default_pw = 'Test@123'
    created = 0
    reset = 0

    def ensure_password(name, utype, email=None, parent_admin=None, parent_trader=None):
        nonlocal created, reset
        if not user_exists(name, utype):
            if create_user(name, default_pw, utype, email, parent_admin, parent_trader):
                created += 1
        else:
            # Reset password for users who have never logged in (still have old random pw)
            existing = get_user(name, utype)
            if existing and not existing.get('last_login'):
                if update_user_password(name, utype, default_pw):
                    reset += 1

    for admin_name, admin_data in hierarchy.get('admins', {}).items():
        ensure_password(admin_name, 'admin', admin_data.get('email'))
        for trader_name, trader_data in admin_data.get('traders', {}).items():
            ensure_password(trader_name, 'trader', trader_data.get('email'), admin_name)
            for client in trader_data.get('clients', []):

    if created or reset:
        print(f"[AUTH] Provisioned {created} new, reset {reset} existing users to default password")

def _bg_provision()
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def _bg_provision():
    try:
        provision_hierarchy_passwords()
    except Exception as _prov_exc:
        print(f"[STARTUP] WARNING: provision_hierarchy_passwords failed: {_prov_exc}")
```

```
def require_api_key(f)
```

Decorator to require valid API key for endpoint access.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.

Step by step (top-level body)

1. Defines a nested function `decorated_function(...)`.
2. **return** `decorated_function`.

Code (copy-paste safe)

```
def require_api_key(f):
    """Decorator to require valid API key for endpoint access."""
    @wraps(f)
    def decorated_function(*args, **kwargs):
        api_key = request.headers.get('X-API-Key')

        log_action('ADMIN_ACCESS', 'admin', 'super_admin', client_ip, f"Endpoint: {request.endpoint}")
        return f(*args, **kwargs)
    return decorated_function
```

```
def require_role(*allowed_roles)
```

Decorator to require specific roles via session authentication.

Why these Python concepts were used

- ***allowed_roles** — Accepts a variable number of positional arguments. Most common reason: the function forwards them to another callable, or it operates on a list whose length is not fixed up front.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.

Step by step (top-level body)

1. Defines a nested function decorator(...).

2. **return** decorator.

Code (copy-paste safe)

```
def require_role(*allowed_roles):
    """Decorator to require specific roles via session authentication."""
    def decorator(f):
        @wraps(f)
        def decorated_function(*args, **kwargs):
            session_token = request.cookies.get('session_token')

            if not session_token:
                return jsonify({"status": "error", "message": "Authentication required"}), 401

            session_info = validate_session(session_token)
            if not session_info:
                return jsonify({"status": "error", "message": "Invalid or expired session"}), 401

            user_type = session_info.get('user_type')
            if user_type not in allowed_roles:
                log_action('ACCESS_DENIED', user_type, session_info.get('user_identifier'),
                           get_remote_address(), f"Required roles: {allowed_roles}", False)
                return jsonify({"status": "error",
                               "message": "Access denied. Insufficient permissions."}), 403

            request.session_user = session_info
            return f(*args, **kwargs)
        return decorated_function
    return decorator
```

```
def require_session(f)
```

Decorator to require valid session for web access.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.

Step by step (top-level body)

1. Defines a nested function decorated_function(...).

2. **return** decorated_function.

    return {'home_url': '/'}

```

```

@app.route('/maintenance')
def maintenance_page()

```

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `session_token = request.cookies.get('session_token')`.
2. **if** `session_token`: branches conditionally.
3. **return** `render_template('maintenance.html')`.

Code (copy-paste safe)

```

def maintenance_page():
    session_token = request.cookies.get('session_token')
    if session_token:
        try:
            session_info = validate_session(session_token)
            if session_info and session_info.get('user_type') in MAINTENANCE_EXEMPT:
                user_type = session_info.get('user_type')
                user_id = session_info.get('user_identifier')
                if user_type == 'super_admin':
                    return redirect('/super_admin')
                elif user_type == 'bef_admin':
                    return redirect('/bef_admin')

    if session_user.get('user_type') != 'admin' or session_user.get('user_identifier') != admin_name:
        return redirect('/')
    return render_template('admin_dashboard.html', admin_name=admin_name)

@app.route('/financial_overview')
@require_session
def financial_overview()
```

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@require_session** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **dict comprehension** — Builds a dict in one expression (`{k: v for k, v in items}`) — same intent as a list comprehension but for mappings.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to `sum`, `any`, `all`, or `max` where the intermediate list would be wasted.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns `session_user = request.session_user`.
2. **if** `session_user.get('user_type') not in ('super_admin', 'bef_admin', '...':` branches conditionally.

@app.route('/payout_history')
@require_session
def payout_history()

```

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@require_session** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with `append`, and clearer about intent: this is a transform, not a side-effecting loop.

Step by step (top-level body)

1. Assigns `session_user = request.session_user`.
2. **if** `session_user.get('user_type') not in ('super_admin', 'bef_admin', '...: branches conditionally.`
3. Assigns `start_date_str = request.args.get('start_date')`.
4. Assigns `end_date_str = request.args.get('end_date')`.
5. Assigns `start_date = None`.
6. **if** `start_date_str`: branches conditionally.
7. Assigns `end_date = None`.
8. **if** `end_date_str`: branches conditionally.
9. Assigns `prop_firm_filter = request.args.get('prop_firm')`.
10. Assigns `profile_filter = request.args.get('profile', 'ALL')`.
11. **if** `session_user.get('user_type') == 'bef_admin'`: branches conditionally.
12. **if** `session_user.get('user_type') == 'kwok_admin'`: branches conditionally.
13. Assigns `overview_data = calculate_propfirm_overview()`.
14. Assigns `sorted_prop_firms = sorted(overview_data.keys())`.
15. ... and 4 more statement(s) in the body.

```

@app.route('/trader_performance')
@require_session
def trader_performance()

```

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@require_session** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.

Step by step (top-level body)

1. Assigns `session_user = request.session_user`.
2. **if** `session_user.get('user_type') == 'kwok_admin':` branches conditionally.
3. **if** `session_user.get('user_type') not in ('super_admin', 'bef_admin'):` branches conditionally.
4. Assigns `profile_filter = request.args.get('profile', 'ALL')`.
5. **if** `session_user.get('user_type') == 'bef_admin':` branches conditionally.
6. Assigns `traders_data = calculate_trader_stats(profile_filter=profile_filter)`.
7. Assigns `ut = session_user.get('user_type')`.
8. **return** `render_template('trader_performance.html', traders=traders_data, se...`

Code (copy-paste safe)

```

def trader_performance():
    session_user = request.session_user
    if session_user.get('user_type') == 'kwok_admin':
        return redirect('/kwok_admin')
    if session_user.get('user_type') not in ('super_admin', 'bef_admin'):
        return redirect('/')

    profile_filter = request.args.get('profile', 'ALL')
    # BEF admin always sees only BEF profile
    if session_user.get('user_type') == 'bef_admin':
        profile_filter = 'BEF'
    traders_data = calculate_trader_stats(profile_filter=profile_filter)
    ut = session_user.get('user_type')
    return render_template('trader_performance.html', traders=traders_data, selected_profile=profile_filter,
                          is_bef_admin=(ut == 'bef_admin'), is_kwok_admin=(ut == 'kwok_admin'))

@app.route('/trader/<trader_name>')
@require_session
def trader_dashboard(trader_name)

```

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@require_session** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

Step by step (top-level body)

1. Assigns `session_user = request.session_user`.
2. **try** block with 1 **except** clause.
3. Assigns `trader_email = ''`.
4. Assigns `trader_admin = ''`.
5. **try** block with 1 **except** clause.
6. **if** `session_user.get('user_type') in ('super_admin', 'bef_admin', 'kwok...)` branches conditionally.
7. **if** `session_user.get('user_type') == 'admin':` branches conditionally.
8. **if** `session_user.get('user_type') != 'trader' or session_user.get('user...)` branches conditionally.
9. **return** `render_template('trader_dashboard.html', trader_name=trader_name, t...`

Code (copy-paste safe)

```
def trader_dashboard(trader_name):
    session_user = request.session_user

def get_filtered_hierarchy(user_type, user_identifier)

```

Returns hierarchy filtered based on user role: - super_admin: sees everything - admin: sees only their traders and clients - trader: sees only their clients - client: sees only themselves

Why these Python concepts were used

- **list comprehension** — Builds a list in a single expression ([f(x) for x in xs]). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns full_hierarchy = hierarchy.
2. if user_type == 'super_admin': branches conditionally.
3. if user_type == 'kwok_admin': branches conditionally.

4. if user_type == 'bef_admin': branches conditionally.
5. if user_type == 'admin': branches conditionally.
6. if user_type == 'trader': branches conditionally.
7. if user_type == 'client': branches conditionally.
8. return {'admins': {}}

Code (copy-paste safe)

```
def get_filtered_hierarchy(user_type, user_identifier):

    return {'admins': {}}

```

```

@app.route('/api/hierarchy')
def get_hierarchy()

```

Returns hierarchy filtered by user's role.

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **list comprehension** — Builds a list in a single expression ([f(x) for x in xs]). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.

- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `session_token = request.cookies.get('session_token')`.
2. `if not session_token:` branches conditionally.
3. Assigns `user_type = 'super_admin'`.
4. Assigns `user_identifier = 'baller'`.
5. `if session_token:` branches conditionally.
6. Lazy import from `config.hierarchy`.
7. Calls `reload_hierarchy(...)` for its side effect.
8. Assigns `filtered = get_filtered_hierarchy(user_type, user_identifier)`.
9. Lazy import from `dashboard.database`.
10. Imports `copy` (lazy import inside the function).
11. Assigns `all_identities = get_all_client_identities()`.
12. Assigns `enriched = copy.deepcopy(filtered)`.
13. `for admin_data in enriched.get('admins', {}).values():` iterates.
14. `if not enriched.get('admins') or all((not admin_data.get('traders', {}):` branches conditionally.
15. ... and 5 more statement(s) in the body.

```

@app.route('/api/super_admin/profit_splits')
@require_session
def get_profit_splits()

```

Return per-client current profit split (in progress) for the super admin dashboard.

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@require_session** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.

- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns session_user = request.session_user.

@app.route('/api/client/lookup', methods=['POST'])
@require_api_key
def api_client_lookup()
```

Look up client hierarchy info by email.

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.

- **@require_api_key** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.

Step by step (top-level body)

1. Assigns `email = request.json.get('email', '').strip()`.
2. **if not email:** branches conditionally.
3. Assigns `client = get_client_by_email(email)`.
4. **if client:** branches conditionally.
5. **return** `(jsonify({'status': 'error', 'message': 'Email not found in system'....`

Code (copy-paste safe)

```
def api_client_lookup():
    """Look up client hierarchy info by email."""
    email = request.json.get('email', '').strip()

    if not email:
        return jsonify({"status": "error", "message": "Email required"}), 400

    client = get_client_by_email(email)
    if client:
        return jsonify({
            "status": "success",
            "client": client['client'],
            "trader": client['trader'],
            "admin": client['admin'],
            "email": client['email']
        })

    return jsonify({"status": "error", "message": "Email not found in system"}), 404

@app.route('/api/check_email', methods=['GET', 'POST', 'OPTIONS'], strict_slashes=False)
def api_check_email():

    Check whether an email (or username) exists in the system. Accepts both GET (?email=...) and POST (JSON body: {"email": "..."}). Requires X-API-Key header (accepts both 'full' and 'readonly' scoped keys). Response (200): {"exists": true, "user_type": "client", "username": "John Doe"} {"exists": false}
```

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.

Step by step (top-level body)

1. **if request.method == 'OPTIONS':** branches conditionally.
2. Assigns `api_key = request.headers.get('X-API-Key')`.
3. Assigns `client_ip = get_remote_address()`.
4. **if not api_key:** branches conditionally.

5. Assigns `user_info = validate_api_key(api_key)`.
6. **if** not `user_info`: branches conditionally.
7. **if** `request.method == 'POST'`: branches conditionally (with an **else**/**elif** arm).
8. **if** not `email`: branches conditionally.
9. Lazy import from `dashboard.database`.
10. Lazy import from `config.hierarchy`.
11. Defines a nested function `_find_client_email(...)`.
12. Assigns `found = _find_client_email(email)`.
13. **if** `found`: branches conditionally.
14. **return** `jsonify({'exists': False})`.

Code (copy-paste safe)

```
def api_check_email():
    """

```

GET — Return all emails registered in the system (each entry includes exists: true). POST — Bulk check: pass {"emails": ["a@b.com", ...]} and get back exists true/false per email. Requires X-API-Key header (accepts both 'full' and 'readonly' scoped keys). GET query params: ?user_type=client|trader|admin — filter by role (default: all) ?active_only=true — only include active accounts (default: true) GET response: {"count": 2, "emails": [{"email": "john@example.com", "username": "John", "user_type": "client", "exists": true}, ...]} POST response: {"results": [{"email": "john@example.com", "exists": true, "user_type": "client", "username": "John"}, {"email": "unknown@x.com", "exists": false}]}

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.

Step by step (top-level body)

1. `if request.method == 'OPTIONS':` branches conditionally.
2. Assigns `api_key = request.headers.get('X-API-Key')`.

3. Assigns `client_ip = get_remote_address()`.
4. `if not api_key`: branches conditionally.
5. Assigns `user_info = validate_api_key(api_key)`.
6. `if not user_info`: branches conditionally.
7. Lazy import from `dashboard.database`.
8. Lazy import from `config.hierarchy`.
9. Defines a nested function `_all_hierarchy_clients(...)`.
10. Defines a nested function `_find_client_email(...)`.
11. `if request.method == 'POST'`: branches conditionally.
12. Assigns `active_only = request.args.get('active_only', 'true').lower() != 'false'`.
13. Assigns `seen_emails = set()`.
14. Assigns `results = []`.
15. ... and 4 more statement(s) in the body.

Code (copy-paste safe)

```
def api_list_emails():
    """

def _drop_balance_deals(deals)

```

Remove internal-transfer style MT5 deals (BALANCE/CREDIT) from a pushed deal list. Requirement: these internal transfers should "not exist" for the dashboard: they should not be stored, displayed, or used in server-side calculations.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with `append`, and clearer about intent: this is a transform, not a side-effecting loop.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.

Step by step (top-level body)

1. **if** not deals: branches conditionally.
2. **if** not isinstance(deals, list): branches conditionally.
3. Defines a nested function `_is_internal(...)`.
4. Assigns `filtered = [d for d in deals if not _is_internal(d)]`.
5. Assigns `dropped = len(deals) - len(filtered)`.
6. **return** (filtered, dropped).

Code (copy-paste safe)

```

def _drop_balance_deals(deals):
    """
    Remove internal-transfer style MT5 deals (BALANCE/CREDIT) from a pushed deal list.

@app.route('/api/client/push', methods=['POST'])
@limiter.limit('60 per minute')
def api_client_push()

```

Public endpoint - push data using client email only (no API key). Automatically looks up hierarchy from email. Recalculates statistics using MT5 deals/account data if provided.

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@limiter.limit** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.

- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

@app.route('/api/client/migrate_sheet', methods=['POST'])
@limiter.limit('10 per minute')
def api_migrate_sheet()

```

Public endpoint - migrate data from Google Sheets using client email. Fetches data from Google Sheet and pushes it to the dashboard.

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@limiter.limit** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns data = request.json.
2. Assigns email = data.get('email', '').strip().lower().
3. Assigns sheet_url = data.get('sheet_url', '').strip().
4. **if** not email: branches conditionally.
5. **if** not sheet_url: branches conditionally.
6. Assigns client_info = get_client_by_email(email).
7. **if** not client_info: branches conditionally.
8. Assigns admin_id = client_info['admin'].
9. Assigns trader_id = client_info['trader'].
10. Assigns client_id = client_info['client'].
11. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

@app.route('/api/client/watermark_history/<client_id>')
@require_session
def api_get_watermark_history(client_id)

```

Get daily watermark history for a client. Restricted: Clients can only see their own waterlog history.

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@require_session** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns `session_user = request.session_user`.
2. Assigns `user_type = session_user.get('user_type')`.
3. Assigns `user_id = session_user.get('user_identifier')`.
4. Assigns `is_authorized = False`.
5. **if** `user_type` in `['super_admin', 'admin', 'trader', 'kwok_admin']`: branches conditionally (with an **else/elif** arm).
6. **if** `not is_authorized`: branches conditionally.
7. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

@app.route('/api/admin/create_user', methods=['POST'])
@require_role('super_admin')
@limiter.limit('20 per hour')
def api_create_user()

```

Create a new user account.

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@require_role** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **@limiter.limit** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.

• **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns data = request.json.
2. Assigns username = data.get('username').
3. Assigns user_type = data.get('user_type').
4. Assigns email = data.get('email').
5. Assigns password = data.get('password').
6. if not password: branches conditionally.
7. Assigns parent_admin = data.get('parent_admin').
8. Assigns parent_trader = data.get('parent_trader').
9. if not username or not user_type: branches conditionally.
10. if user_type not in ['admin', 'trader', 'client']: branches conditionally.
11. Assigns user_db_exists = user_exists(username, user_type).
12. Assigns hierarchy_exists = False.
13. if user_type == 'admin': branches conditionally (with an **else/elif** arm).
14. if user_db_exists and hierarchy_exists: branches conditionally.
15. ... and 4 more statement(s) in the body.

```

@app.route('/api/kyc/portfolio', methods=['GET'])
@require_session
def api_kyc_portfolio()

```

Get combined portfolio stats across all KYC-linked accounts. Reads directly from stored statistics (same as client Stats tab) for consistency.

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@require_session** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns `session_user = request.session_user`.
2. Assigns `user_type = session_user.get('user_type')`.
3. Assigns `user_id = session_user.get('user_identifier', '')`.
4. Assigns `client_id = request.args.get('client_id', '')`.
5. Assigns `is_bef = user_type == 'bef_admin'`.
6. **if** `user_type` in ('super_admin', 'bef_admin', 'kwok_admin', 'admin', 't...': branches conditionally (with an **else/elif** arm).
7. **if** `not is_kyc_primary(client_id)`: branches conditionally.
8. Assigns `from_date = request.args.get('from', '')`.
9. Assigns `to_date = request.args.get('to', '')`.
10. Assigns `accounts = get_all_kyc_accounts(client_id)`.
11. Lazy import from `dashboard.financial_overview`.
12. Defines a nested function `parse_date_safe(...)`.
13. Assigns `filter_from = parse_date_safe(from_date)` if `from_date` else `None`.
14. Assigns `filter_to = parse_date_safe(to_date)` if `to_date` else `None`.
15. ... and 16 more statement(s) in the body.

@app.route('/api/add_admin', methods=['POST'])
def api_add_admin()

```

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.

Step by step (top-level body)

1. Assigns `name = request.json.get('name')`.
2. Assigns `email = request.json.get('email', '')`.
3. **if** `not name`: branches conditionally.
4. **if** `add_admin(name, email)`: branches conditionally.
5. **return** `(jsonify({'status': 'error', 'message': 'Admin exists'}), 400)`.

Code (copy-paste safe)

```
def api_add_admin():
    name = request.json.get('name')
    email = request.json.get('email', '')
    if not name: return jsonify({"status": "error", "message": "Name required"}), 400

    if add_admin(name, email):
        log_action('ADD_ADMIN', 'system', name, get_remote_address())
        return jsonify({"status": "success"})
    return jsonify({"status": "error", "message": "Admin exists"}), 400

@app.route('/api/delete_user', methods=['POST'])
@require_role('super_admin')
def api_delete_user():
```

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@require_role** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `data = request.json`.
2. Assigns `user_type = data.get('type')`.
3. Assigns `name = data.get('name')`.
4. Assigns `admin = data.get('admin')`.
5. Assigns `trader = data.get('trader')`.
6. **if** `not user_type` or `not name`: branches conditionally.
7. Assigns `result = False`.
8. **if** `user_type == 'admin'`: branches conditionally (with an **else/elif** arm).
9. **if** `result`: branches conditionally (with an **else/elif** arm).

Code (copy-paste safe)

```

@app.route('/api/assign_client_trader', methods=['POST'])
@require_session
def api_assign_client_trader()

```

Reassign a client to a new trader and persist to: - hierarchy JSON (reassign_client_trader — auto-creates lane if needed) - user_credentials (parent_trader/parent_admin) - clients_data.identity (admin/trader fields, if record exists)

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@require_session** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns session_user = request.session_user.
2. if session_user.get('user_type') not in ('super_admin', 'bef_admin'): branches conditionally.
3. Assigns data = request.json or {}.

4. Assigns `client_name = (data.get('client_name') or '').strip()`.

@app.route('/api/client/delete_evaluation', methods=['POST'])
@limiter.limit('30 per minute')
def api_delete_evaluation()
```

Delete an evaluation row with history tracking. Only super_admin users can delete evaluation rows. The data is removed from current view but can be recovered from version history.

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@limiter.limit** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses `x` if `cond` else `y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns `session_token = request.cookies.get('session_token')`.
2. **if** `not session_token`: branches conditionally.
3. Assigns `session_info = validate_session(session_token)`.

4. **if** not session_info: branches conditionally.
5. **if** session_info.get('user_type') != 'super_admin': branches conditionally.
6. Assigns data = request.json.
7. Assigns email = data.get('email', "").strip().lower().
8. Assigns evaluation_index = data.get('index').
9. **if** not email: branches conditionally.
10. **if** evaluation_index is None: branches conditionally.
11. Lazy import from config.hierarchy.
12. Assigns client_info = get_client_by_email(email).
13. **if** not client_info: branches conditionally.
14. Assigns client_id = client_info['client'].
15. ... and 27 more statement(s) in the body.

```

@app.route('/api/client/check_mt5_auto_populate/<client_id>', methods=['GET'])
@require_session
def check_mt5_auto_populate(client_id)

```

On dashboard load, check if MT5 values need auto-population. Returns status and suggestion for initialization.

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@require_session** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.

Step by step (top-level body)

1. Assigns session_user = request.session_user.

```

@app.route('/api/data')
@limiter.limit('180 per minute')
def get_data()

```

Get client data - requires authentication and role-based access.

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@limiter.limit** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `client_id = request.args.get('client_id')`.
2. Assigns `session_token = request.cookies.get('session_token')`.
3. **if** `not session_token`: branches conditionally (with an **else/elif** arm).
4. **if** `client_id`: branches conditionally.
5. **return** `jsonify({'status': 'success', 'deals': [], 'positions': [], 'accoun....`

Code (copy-paste safe)

```

```

```

@app.route('/api/client/export_csv')
def export_client_csv()

```

Export client evaluation data as CSV download.

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **list comprehension** — Builds a list in a single expression ([f(x) for x in xs]). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.

Step by step (top-level body)

1. Imports csv (lazy import inside the function).
2. Imports io (lazy import inside the function).
3. Assigns client_id = request.args.get('client_id').

4. **if** not client_id: branches conditionally.
5. Assigns session_token = request.cookies.get('session_token').
6. Assigns api_key = request.headers.get('X-API-Key').
7. **if** session_token: branches conditionally (with an **else/elif** arm).
8. **if** not can_access_client(user_type, user_identifier, client_id): branches conditionally.
9. Assigns data = get_client_data(client_id).
10. **if** not data: branches conditionally.
11. Assigns evaluations = data.get('evaluations', []).
12. **if** not evaluations: branches conditionally.
13. Assigns DASHBOARD_COLUMN_ORDER = ['Prop Firm', 'Account Size', 'Date Purchased', 'Fee', 'D....
14. Assigns all_keys = set().
15. ... and 19 more statement(s) in the body.

def _parse_date_str(val)
```

Try to parse a date string from evaluation data. Returns YYYY-MM-DD or None.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

Step by step (top-level body)

1. **if** not val: branches conditionally.
2. Assigns val = str(val).strip().rstrip('.').
3. **if** not val or len(val) < 3: branches conditionally.
4. **if** val[0].isalpha() and '/' not in val and '-' not in val: branches conditionally.
5. Assigns normalized = val.replace('.', '/').replace('//', '/').
6. **while** normalized and (not normalized[0].isdigit()): loops until the condition is false.
7. **if** not normalized: branches conditionally.
8. **for** fmt in ('%Y-%m-%d', '%m/%d/%Y', '%m/%d/%y', '%m-%d-%Y', '%m-%d-%y...: iterates.
9. Assigns parts = normalized.split('/').
10. **if** len(parts) == 2: branches conditionally.
11. **return** None.

Code (copy-paste safe)

```

def _parse_date_str(val):

        return dates[-1]
    return dates[-1]
```

```
def run_quality_scan(target_client=None)
```

Automated quality scan: checks every client's data for SOP violations. Returns list of per-client scan results with issues and health scores. If target_client is given, only scan that one client.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Lazy import from `config.hierarchy`.
2. Lazy import from `dashboard.database`.
3. Assigns `all_clients = [target_client] if target_client else hierarchy_get_all_c....`

Return all clients sorted by absolute discrepancy (highest first).

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@require_role** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Lazy import from dashboard.database.
2. **with** get_connection(): enters a context manager.
3. Assigns results = [].
4. **for** row in rows: iterates.
5. Calls results.sort(...) for its side effect.
6. **return** jsonify({'status': 'success', 'clients': results}).

Code (copy-paste safe)

```

@app.route('/api/quality/results')
@require_role('super_admin', 'bef_admin')
def api_quality_results():

```

Get quality scan results. Supports ?date=, ?start=&end= for ranges. Super admin only.

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@require_role** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

```

```
def compute_admin_tracker_payload(admin_name: str, date: str)
```

Compute admin-tracker payload (shared by UI + Slack summaries).

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `admin_name: str`, `date: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with `append`, and clearer about intent: this is a transform, not a side-effecting loop.
- **dict comprehension** — Builds a dict in one expression (`{k: v for k, v in items}`) — same intent as a list comprehension but for mappings.
- **set comprehension** — Builds a set in one expression — usually to deduplicate the result of a transform.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to `sum`, `any`, `all`, or `max` where the intermediate list would be wasted.
- **lambda** — Uses a single-expression anonymous function — typically as the `key=` for a `sort`, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Lazy import from `config.hierarchy`.
2. Lazy import from `dashboard.database`.
3. Lazy import from `dashboard.notes_service`.
4. Imports `json` (lazy import inside the function).
5. Assigns `excluded_traders = set(_json.loads(get_setting('summary_tracker_excluded_tra...`
6. Assigns `excluded_clients = set(_json.loads(get_setting('summary_tracker_excluded_cli...`
7. Assigns `clients = []`.
8. **for** `client_id` in `hierarchy_get_all_clients()`: iterates.
9. Calls `clients.sort(...)` for its side effect.
10. Assigns `scan_results = get_quality_scan_results()` or `[]`.
11. Assigns `scan_by_client = {r.get('client_id'): r for r in scan_results if r.get('cl...`
12. Assigns `admin_issues = []`.

13. Defines a nested function `_add_issue(...)`.

14. Defines a nested function `_norm_pf(...)`.

15. ... and 18 more statement(s) in the body.

def api_admin_tracker()

```

Admin tracking dashboard: aggregate admin-owned issues derived from client state and quality scan.

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@require_role** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **dict comprehension** — Builds a dict in one expression (`{k: v for k, v in items}`) — same intent as a list comprehension but for mappings.
- **set comprehension** — Builds a set in one expression — usually to deduplicate the result of a transform.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

@app.route('/api/quality/admin_tracker')
@require_role('super_admin', 'bef_admin')
def api_quality_admin_tracker()

```

Super-admin view of admin tracker issues across admins (quality dashboard source of truth).

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@require_role** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def api_quality_admin_tracker():
    """Super-admin view of admin tracker issues across admins (quality dashboard source of truth)."""
    try:
        from config.hierarchy import get_all_clients as hierarchy_get_all_clients, get_client_profile
        admins = set()
        for cid in hierarchy_get_all_clients():
            p = get_client_profile(cid) or {}
            a = str(p.get('admin') or '').strip()
            if a:
                admins.add(a)
        admin = (request.args.get('admin') or '').strip()
        date = request.args.get('date', datetime.now().strftime('%Y-%m-%d'))

        # Reuse the existing admin tracker endpoint logic by calling the local view function's helper th
        # We simply invoke /api/admin/tracker-style computation by issuing internal HTTP is overkill; ins
        # is not possible cleanly. So we request per-admin via the public function by recreating minimal
        # Pragmatic: call /api/admin/tracker endpoint from frontend for a single admin; for all admins, l
        # by delegating to the endpoint itself is avoided. Instead, we reuse the DB-backed quality + cli
        # calling the /api/admin/tracker route through WSGI is out of scope.

        # Implementation: make N calls by recomputing via querystring by temporarily setting request args
        # Therefore, we implement a small loop by calling the public endpoint over HTTP is also not allow
        # So: return the list of admins + let the quality dashboard fetch each admin in parallel.
        # This keeps server logic correct and avoids duplicating the computation again.
        result_admins = sorted(admins)

@app.route('/api/quality/admin_issues')
@require_role('admin', 'super_admin')
def api_admin_issues():
```

Return latest quality scan results filtered for a specific admin's traders/clients. Admin role only.

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@require_role** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. try block with 1 **except** clause.

Code (copy-paste safe)

```
def api_admin_issues():
    """Return latest quality scan results filtered for a specific admin's traders/clients. Admin role on"""
    try:

@app.route('/api/quality/scan_dates')
@require_role('super_admin', 'bef_admin')
def api_quality_scan_dates():
```

Get list of all dates that have scan results.

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@require_role** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def api_quality_scan_dates():
    """Get list of all dates that have scan results."""
    try:
        from dashboard.database import get_connection
        with get_connection() as conn:
            cursor = conn.cursor()
            cursor.execute('SELECT DISTINCT scan_date FROM quality_scan_results ORDER BY scan_date DESC')
            dates = [row['scan_date'] for row in cursor.fetchall()]
            return jsonify({'status': 'success', 'dates': dates})
    except Exception as e:
        return jsonify({'status': 'success', 'dates': []})

@app.route('/api/quality/summary_status')
@require_role('super_admin', 'bef_admin')
def api_summary_status()
```

Get daily summary submission status for all clients, grouped by trader.

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@require_role** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **dict comprehension** — Builds a dict in one expression (`{k: v for k, v in items}`) — same intent as a list comprehension but for mappings.

- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Lazy import from config.hierarchy.
2. Lazy import from dashboard.database.
3. Imports json (lazy import inside the function).
4. Lazy import from datetime.

            return None, (jsonify({'status': 'error', 'message': 'Access denied'}), 403)

    # super_admin / bef_admin: allow any trader
    return trader_name, None

```

```
def _clients_for_trader(trader_name)
```

Return the list of client names managed by the given trader across all admins.

Why these Python concepts were used

- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns names = [].
2. Assigns seen = set().
3. for admin_data in hierarchy.get('admins', {}).values(): iterates.
4. return names.

Code (copy-paste safe)

```
def _clients_for_trader(trader_name):
    """Return the list of client names managed by the given trader across all admins."""
    names = []
    seen = set()
    for admin_data in hierarchy.get('admins', {}).values():
        tdata = (admin_data.get('traders') or {}).get(trader_name)
        if not tdata:
            continue
        for c in tdata.get('clients', []) or []:
            nm = c.get('name') if isinstance(c, dict) else c
            if nm and nm not in seen:
                seen.add(nm)
                names.append(nm)
    return names

@app.route('/api/quality/trader_issues')
@require_role('trader', 'admin', 'super_admin', 'bef_admin', 'kwok_admin')
def api_trader_issues()
```

Latest quality scan issues filtered to a single trader's clients. Traders see only themselves; admins see their own traders; super_admin / bef_admin can pass ?trader=<name>. Clients with no scan record are returned with total_issues=0 so the UI can show "all clear" rows too.

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@require_role** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **set comprehension** — Builds a set in one expression — usually to deduplicate the result of a transform.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. try block with 1 **except** clause.

Code (copy-paste safe)

```
def api_trader_issues():
    """Latest quality scan issues filtered to a single trader's clients.

@app.route('/api/checklist/submit', methods=['POST'])
@require_session
```

```
def api_submit_checklist()
```

Submit a daily checklist (per client).

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@require_session** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Lazy import from dashboard.database.
2. Assigns session_user = request.session_user.
3. Assigns user_type = session_user.get('user_type').
4. Assigns user_identifier = session_user.get('user_identifier').
5. Assigns data = request.json.
6. Assigns checklist_type = data.get('checklist_type', 'daily_summary').
7. Assigns client_id = data.get('client_id', '').
8. Assigns items = data.get('items', []).
9. **if not items**: branches conditionally.
10. Assigns today = datetime.now().strftime('%Y-%m-%d').
11. Calls save_daily_checklist(...) for its side effect.
12. Calls log_action(...) for its side effect.
13. **return** jsonify({'status': 'success', 'message': 'Daily summary saved'}).

Code (copy-paste safe)

```
def api_submit_checklist():
    """Submit a daily checklist (per client)."""
    from dashboard.database import save_daily_checklist
    session_user = request.session_user
    user_type = session_user.get('user_type')
    user_identifier = session_user.get('user_identifier')

    data = request.json
    checklist_type = data.get('checklist_type', 'daily_summary')
    client_id = data.get('client_id', '')
    items = data.get('items', [])

    if not items:
        return jsonify({'status': 'error', 'message': 'No items provided'}), 400

    today = datetime.now().strftime('%Y-%m-%d')
    save_daily_checklist(today, user_identifier, user_type, checklist_type, items,
                        get_remote_address(), client_id=client_id)
```

```

log_action('CHECKLIST_SUBMIT', user_type, user_identifier, get_remote_address(),
          f"{checklist_type} for {client_id}: {len(items)} sections")

return jsonify({'status': 'success', 'message': 'Daily summary saved'})

@app.route('/api/checklist/status')
@require_session
def api_checklist_status():
    Get checklist status for today (or specified date).

```

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@require_session** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.

Step by step (top-level body)

1. Lazy import from `dashboard.database`.
2. Assigns `session_user = request.session_user`.
3. Assigns `user_identifier = session_user.get('user_identifier')`.
4. Assigns `user_type = session_user.get('user_type')`.
5. Assigns `date = request.args.get('date', datetime.now().strftime('%Y-%m-%...'))`.
6. Assigns `client_id = request.args.get('client_id', '')`.
7. **if** `user_type` in `('super_admin', 'bef_admin')`: branches conditionally (with an **else/elif** arm).
8. **if** `client_id`: branches conditionally.
9. **return** `jsonify({'status': 'success', 'date': date, 'checklists': checklists})`.

Code (copy-paste safe)

```

def api_checklist_status():
    """Get checklist status for today (or specified date)."""
    from dashboard.database import get_daily_checklists
    session_user = request.session_user
    user_identifier = session_user.get('user_identifier')
    user_type = session_user.get('user_type')

    date = request.args.get('date', datetime.now().strftime('%Y-%m-%d'))
    client_id = request.args.get('client_id', '')

    if user_type in ('super_admin', 'bef_admin'):

@require_role('admin', 'super_admin', 'bef_admin', 'kwok_admin')
def api_admin_summary_signoff():

```

Admin sign-off: confirm trader summary reviewed + sent to client (persisted like trader tracking).

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@require_role** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Lazy import from dashboard.database.
2. Assigns session_user = request.session_user.
3. Assigns user_type = session_user.get('user_type').
4. Assigns session_id = (session_user.get('user_identifier') or "").strip().

@app.route('/api/quality/scorecard')
@require_role('super_admin', 'bef_admin')
def api_weekly_scorecard()

```

Generate weekly scorecard aggregating quality scan data per trader.

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@require_role** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **list comprehension** — Builds a list in a single expression ([f(x) for x in xs]). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.

- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.

- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

Generate a text summary of today's dashboard state for Discord/team sharing.

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@require_role** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **dict comprehension** — Builds a dict in one expression (`{k: v for k, v in items}`) — same intent as a list comprehension but for mappings.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

@app.route('/api/settings/slack_webhook', methods=['GET'])
@require_role('super_admin')
def api_get_slack_webhook()

```

Get the current Slack webhook URL (masked). Super admin only.

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@require_role** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Lazy import from dashboard.database.
2. Assigns url = get_setting('slack_webhook_url').
3. if url: branches conditionally.
4. return jsonify({'status': 'success', 'configured': False, 'masked_url': ''}).

Code (copy-paste safe)

```

def api_get_slack_webhook():
    """Get the current Slack webhook URL (masked). Super admin only."""
    from dashboard.database import get_setting
    url = get_setting('slack_webhook_url')
    if url:
        # Mask the URL for display – show first 40 chars + last 6
        masked = url[:40] + '...' + url[-6:] if len(url) > 50 else url
        return jsonify({'status': 'success', 'configured': True, 'masked_url': masked})
    return jsonify({'status': 'success', 'configured': False, 'masked_url': ''})

@app.route('/api/settings/slack_webhook', methods=['POST'])
@require_role('super_admin')
def api_set_slack_webhook()

```

Set the Slack webhook URL. Super admin only.

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@require_role** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Lazy import from dashboard.database.
2. Assigns data = request.get_json(force=True).
3. Assigns url = (data.get('url') or '').strip().
4. Assigns user = request.session_user.get('user_identifier', '').
5. **if** url and (not url.startswith('https://hooks.slack.com/')): branches conditionally.
6. Calls set_setting(...) for its side effect.
7. Assigns action = 'configured' if url else 'removed'.
8. Calls log_action(...) for its side effect.
9. **return** jsonify({'status': 'success', 'message': f'Slack webhook {action} s....

Code (copy-paste safe)

```
def api_set_slack_webhook():

@require_role('super_admin')
def api_send_slack_summary():
```

Manually post the daily quality summary to Slack. Super admin only. Accepts optional JSON body: { "test_webhook": "https://hooks.slack.com/..." } to override the target (e.g. send to a DM or test channel instead of main).

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@require_role** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Lazy import from dashboard.scheduler.
2. Assigns data = request.get_json(silent=True) or {}.
3. Assigns test_webhook = (data.get('test_webhook') or '').strip().
4. **if** test_webhook and (not test_webhook.startswith('https://hooks.slack....': branches conditionally.
5. **if** not test_webhook and (not _get_slack_webhook_url()): branches conditionally.
6. **try** block with 1 **except** clause.

def api_set_slack_daily_webhook()

```

Set the Daily Summaries Slack webhook URL. Super admin only.

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.

- **@require_role** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Lazy import from dashboard.database.
2. Assigns data = request.get_json(force=True).
3. Assigns url = (data.get('url') or '').strip().
4. Assigns user = request.session_user.get('user_identifier', '').
5. **if** url and (not url.startswith('https://hooks.slack.com/')): branches conditionally.
6. Calls set_setting(...) for its side effect.
7. Assigns action = 'configured' if url else 'removed'.
8. Calls log_action(...) for its side effect.
9. **return** jsonify({'status': 'success', 'message': f'Daily summaries Slack we....

Code (copy-paste safe)

```
def api_set_slack_daily_webhook():
    """Set the Daily Summaries Slack webhook URL. Super admin only."""
    from dashboard.database import set_setting
    data = request.get_json(force=True)
    url = (data.get('url') or '').strip()
    user = request.session_user.get('user_identifier', '')
    if url and not url.startswith('https://hooks.slack.com/'):
        return jsonify({'status': 'error', 'message': 'Invalid Slack webhook URL.'}), 400
    set_setting('slack_daily_summaries_webhook_url', url, updated_by=user)
    action = 'configured' if url else 'removed'

@app.route('/api/update_data', methods=['POST'])
@limiter.limit('60 per minute')
def update_data():

```

Update client data - supports both session and API key authentication.

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@limiter.limit** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

Handle update with API key authentication (for external API calls).

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **if not identity:** branches conditionally.
2. Assigns `admin_id = identity.get('admin', 'Admin1')`.
3. Assigns `trader_id = identity.get('trader', 'Trader1')`.
4. Assigns `client_id = identity.get('client', 'Client1')`.
5. Assigns `email = identity.get('email', '')`.
6. Assigns `existing_data = get_client_data(client_id)` or `{}`.
7. Assigns `incoming_evals = data.get('evaluations')`.

8. if incoming_evals and len(incoming_evals) > 0: branches conditionally (with an **else/elif** arm).
9. Assigns evaluations = normalize_evaluations(evaluations).
10. Assigns incoming_stats = data.get('statistics', {}).
11. Assigns existing_stats = existing_data.get('statistics', {}).
12. Assigns statistics = existing_stats.copy().
13. Calls statistics.update(...) for its side effect.
14. Assigns existing_hr = existing_stats.get('hedging_review').
15. ... and 15 more statement(s) in the body.

@app.route('/api/admin/generate_key', methods=['POST'])
@require_admin_password
@limiter.limit('10 per hour')
def api_generate_key()

```

Generate a new API key for a trader.

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@require_admin_password** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **@limiter.limit** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.

Step by step (top-level body)

1. Assigns `trader_info = request.json.get('trader_info', {})`.
2. Assigns `admin = trader_info.get('admin')`.
3. Assigns `trader = trader_info.get('trader')`.
4. Assigns `client = trader_info.get('client', '')`.
5. **if** not admin or not trader: branches conditionally.
6. Assigns `api_key = generate_api_key(admin, trader, client)`.
7. **if** api_key: branches conditionally.
8. **return** `(jsonify({'status': 'error', 'message': 'Failed to generate key'}),....`

Code (copy-paste safe)

```
def api_generate_key():
    """Generate a new API key for a trader."""
    trader_info = request.json.get('trader_info', {})
    admin = trader_info.get('admin')

@app.route('/api/trader/push_account', methods=['POST'])
@require_api_key
@limiter.limit('30 per minute')
def push_account_data()
```

Endpoint for traders to push account information.

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@require_api_key** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **@limiter.limit** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `data = request.json`.
2. Assigns `client_id = data.get('client_id') or request.api_user.get('client', '....`

3. Calls `update_client_field(...)` for its side effect.
4. Calls `log_action(...)` for its side effect.
5. **return** `jsonify({'status': 'success', 'message': 'Account data updated'})`.

Code (copy-paste safe)

```
def push_account_data():
    """Endpoint for traders to push account information."""
    data = request.json
    client_id = data.get('client_id') or request.api_user.get('client', 'Client1')

    update_client_field(client_id, 'account', data.get('account', {}))
    log_action('PUSH_ACCOUNT', 'trader', request.api_user.get('trader'), get_remote_address(),
              f"Client: {client_id}")

    return jsonify({"status": "success", "message": "Account data updated"})

@app.route('/api/trader/push_positions', methods=['POST'])
@require_api_key
@limiter.limit('30 per minute')
def push_positions():
```

Endpoint for traders to push current positions.

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@require_api_key** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **@limiter.limit** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `data = request.json`.
2. Assigns `client_id = data.get('client_id') or request.api_user.get('client', '....`
3. Calls `update_client_field(...)` for its side effect.
4. Calls `log_action(...)` for its side effect.
5. **return** `jsonify({'status': 'success', 'message': 'Positions updated'})`.

Code (copy-paste safe)

```
def push_positions():

@require_api_key

```

```
@limiter.limit('30 per minute')
def push_evaluations()
```

Endpoint for traders to push evaluation data.

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@require_api_key** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **@limiter.limit** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns data = request.json.
2. Assigns client_id = data.get('client_id') or request.api_user.get('client', '....

    })

@app.route('/api/admin/all_history', methods=['GET'])
@require_admin_password
def api_get_all_history():
```

Admin endpoint to get all history across all clients.

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@require_admin_password** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.

- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.

Step by step (top-level body)

1. Lazy import from `dashboard.database`.
2. Assigns `limit = request.args.get('limit', 100, type=int)`.
3. **with** `get_connection()`: enters a context manager.

        log_action('CHANGE_PASSWORD', 'admin', 'super_admin', get_remote_address())
        return jsonify({"status": "success", "message": "Password changed successfully"})

    return jsonify({"status": "error", "message": "Failed to change password"}), 500

@app.route('/api/sheet/stats')
@require_session
def get_stats_sheet_data():
    Fetches stats data directly from the Google Sheet.
```

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@require_session** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def get_stats_sheet_data():
    """Fetches stats data directly from the Google Sheet."""
    try:
        data = fetch_stats_data()
        if data:
            return jsonify({"status": "success", "data": data})
        return jsonify({"status": "error", "message": "Failed to fetch stats data"}), 500
    except Exception as e:
        return jsonify({"status": "error", "message": str(e)}), 500
```

```
@app.route('/api/sheet/waterlog')
@require_session
def get_waterlog_sheet_data()
```

Returns the Profit Share History table. Priority: 1. Compute from DB (daily_watermarks + waterlog_periods) — fully offline, updates automatically as daily data is snapshotted. 2. Fall back to live Google Sheet fetch only if no period schedule is stored yet (i.e. before the first import). Query params: ?client_id=<id> — required to identify whose schedule/daily data to use ?sheet_url=<url> — fallback sheet URL for pre-import clients

Why these Python concepts were used

- **@app.route** — Registers this function as a Flask URL handler. The decorator binds the URL pattern (and optional HTTP methods) to the function so Flask can dispatch incoming requests here.
- **@require_session** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

Step by step (top-level body)

1. **try** block with 1 **except** clause.
2. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def get_waterlog_sheet_data():
    """Returns the Profit Share History table.
```

1. Compute from DB (daily_watermarks + waterlog_periods) – fully offline, updates automatically as daily data is snapshotted.
2. Fall back to live Google Sheet fetch only if no period schedule is stored yet (i.e. before the first import).

```
?client_id=<id>    - required to identify whose schedule/daily data to use
?sheet_url=<url>   - fallback sheet URL for pre-import clients
"""
```

```

    except ImportError:
        from watermark_service import save_net_profit_override

    if save_net_profit_override(client_id, from_date, amount):
        return jsonify({"status": "success", "message": "Net profit override saved"})
    return jsonify({"status": "error", "message": "Failed to save override"}), 500

@app.errorhandler(404)
def not_found(e)

```

Why these Python concepts were used

- **@app.errorhandler** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.

Step by step (top-level body)

1. **if** `request.accept_mimetypes.accept_json` and (not `request.accept_mimety...`: branches conditionally.
2. **return** ('Page not found', 404).

Code (copy-paste safe)

```

def not_found(e):
    if request.accept_mimetypes.accept_json and not request.accept_mimetypes.accept_html:
        return jsonify({"status": "error", "message": "Not found"}), 404
    return "Page not found", 404

@app.errorhandler(500)
def internal_server_error(e)

```

Show maintenance page on any 500 Internal Server Error.

Why these Python concepts were used

- **@app.errorhandler** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Imports logging (lazy import inside the function).
2. Calls `logging.error(...)` for its side effect.
3. **if** `request.accept_mimetypes.accept_json` and (not `request.accept_mimety...`: branches conditionally.
4. **return** (`render_template('500.html')`, 500).

Code (copy-paste safe)

```

def internal_server_error(e):

```

```

"""Show maintenance page on any 500 Internal Server Error."""
import logging
logging.error(f"500 error: {e}")
if request.accept_mimetypes.accept_json and not request.accept_mimetypes.accept_html:
    return jsonify({"status": "error", "message": "Internal server error"}), 500
return render_template('500.html'), 500

```

```

@app.errorhandler(Exception)
def unhandled_exception(e)

```

Catch-all for any unhandled exception — skip HTTP exceptions (404, 403, etc.).

Why these Python concepts were used

- **@app.errorhandler** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.

Step by step (top-level body)

1. Lazy import from `werkzeug.exceptions`.
2. `if isinstance(e, HTTPException)`: branches conditionally.
3. Imports `logging` (lazy import inside the function).
4. Calls `logging.exception(...)` for its side effect.
5. `if request.accept_mimetypes.accept_json and (not request.accept_mimety...:` branches conditionally.
6. `return (render_template('500.html'), 500)`.

Code (copy-paste safe)

```

def unhandled_exception(e):
    """Catch-all for any unhandled exception – skip HTTP exceptions (404, 403, etc.)."""
    from werkzeug.exceptions import HTTPException
    if isinstance(e, HTTPException):
        return e
    import logging
    logging.exception(f"Unhandled exception: {e}")
    if request.accept_mimetypes.accept_json and not request.accept_mimetypes.accept_html:
        return jsonify({"status": "error", "message": "An unexpected error occurred"}), 500
    return render_template('500.html'), 500

def run_dashboard()

```

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Calls `print(...)` for its side effect.

2. Calls `print(...)` for its side effect.
3. Calls `print(...)` for its side effect.
4. Calls `print(...)` for its side effect.
5. Calls `print(...)` for its side effect.
6. Calls `print(...)` for its side effect.
7. Calls `print(...)` for its side effect.
8. Calls `print(...)` for its side effect.
9. Calls `print(...)` for its side effect.
10. Calls `print(...)` for its side effect.
11. Calls `app.run(...)` for its side effect.

Code (copy-paste safe)

```
def run_dashboard():
    print(f"\n{' '*60}")
    print("SECURE DASHBOARD API SERVER STARTING")
    print(f"{' '*60}")
    print(f"Database: PostgreSQL (Alembic-managed schema)")
    print(f"Rate Limiting: Enabled")
    print(f>Password Hashing: PBKDF2-SHA256 (100,000 iterations)")
    print(f"API Keys: Hashed with SHA-256")
    print(f"Audit Logging: Enabled")
    print(f"\nClients in database: {get_clients_count()}")
    print(f"{' '*60}\n")
    app.run(host='0.0.0.0', port=5001, debug=True)
```

Checkpoint — what works now. Run the Flask app (`flask --app dashboard.app run`), open <http://localhost:5000>, and you have a working web dashboard. Log in, browse accounts, view payouts and the financial overview. The scheduler is running periodic jobs in the background.

Chapter 12 — Phase 10 — Deployment

Last phase. We add the entry points the production server (Gunicorn) calls, a CLI for managing users, a wrapper around Alembic migrations, the script that bundles the dashboard for deployment to PythonAnywhere, and the PyInstaller build script that packages the desktop companion into a Windows executable.

Files we build in this phase, in order:

- wsgi.py
- gunicorn.conf.py
- build.py

Python concepts you'll meet in this phase

- f-strings (3) · Exceptions (2) · Context managers (with-statements) (2) · Decorators (1) · Flask routes (1) · Comprehensions (1)

Each is explained in Chapter 2 (the primer). The number in parentheses is how many of this phase's files use that concept.

Step 12.1 — Build wsgi.py

What to do. Create the file wsgi.py in your project root and paste in the code shown in this step. The file is **109** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from requirements.txt.

What this file is for. The WSGI entry point. Gunicorn imports the application object from this module in production. Keep it small — its only job is to construct the app and expose it under a stable name.

wsgi.py

109 loc · 0 classes · 2 functions · 2 imports

The WSGI entry point. Gunicorn imports the application object from this module in production. Keep it small — its only job is to construct the app and expose it under a stable name. It defines **2** module-level functions, across **109** lines. Module docstring: *WSGI Entry Point for MT5 Hedging Dashboard*

Module docstring

WSGI Entry Point for MT5 Hedging Dashboard =====
This is the entry point for production WSGI servers like Gunicorn.

Usage: gunicorn wsgi:app gunicorn -c gunicorn.conf.py wsgi:app

For development: `python wsgi.py`

Python concepts demonstrated in this module

• Comprehensions • Context managers (with-statements) • Decorators • Exceptions • Flask routes • f-strings

Imports — what each one is for

```
import os
```

Why imported. Operating-system interface. Path manipulation, environment variables, working-directory operations, exit codes, and thin wrappers around POSIX/Windows syscalls.

Used in this file. `os.environ`, `os.getenv`, `os.path`, `os.path.abspath`, `os.path.dirname`, `os.path.join`

Example. `os.path.join(root, 'subdir', 'file.txt')` # joins with the OS-correct separator

Other common scenarios.

- `os.environ.get('API_KEY')` to read environment variables
- `os.makedirs(path, exist_ok=True)` to create nested directories
- `os.listdir(path)` to list a directory's contents
- `os.remove(path)` / `os.rename(src, dst)` to delete or move a file
- `os.getcwd()` / `os.chdir(path)` to inspect or change the working dir

```
import sys
```

Why imported. Access to the running interpreter — `argv`, `stdin/stdout`, exit codes, the import search path, and the platform name.

Used in this file. `sys.path`, `sys.path.insert`

Example. `sys.exit(1)` # terminate the process with a non-zero status

Other common scenarios.

- `sys.argv[1:]` reads the command-line arguments
- `sys.path.insert(0, 'extra')` prepends to the import search path
- `sys.stderr.write(msg)` writes to standard error
- `sys.platform` tells you 'win32', 'linux', or 'darwin'
- `sys.modules` is the global cache of already-imported modules

Functions

```
def _maintenance_fallback(envron, start_response)
```

Static WSGI app returned when Flask itself fails to load.

Step by step (top-level body)

1. Assigns `_html = open(os.path.join(os.path.dirname(os.path.abspath(__file__)), ...`

2. Assigns status = '500 Internal Server Error'.
3. Assigns headers = [('Content-Type', 'text/html; charset=utf-8'), ('Content-....
4. Calls start_response(...) for its side effect.
5. **return** [_html].

Code (copy-paste safe)

```
def _maintenance_fallback(envron, start_response):
    """Static WSGI app returned when Flask itself fails to load."""
    _html = open(
        os.path.join(os.path.dirname(os.path.abspath(__file__)),
                     'dashboard', 'templates', '500.html'),
        'rb'
    ).read()
    status = '500 Internal Server Error'
    headers = [('Content-Type', 'text/html; charset=utf-8'),
               ('Content-Length', str(len(_html)))]
    start_response(status, headers)
    return [_html]
```

```
def configure_app(app)
```

Apply production-specific configurations.

Step by step (top-level body)

1. Lazy import from config.production.
2. Assigns config = get_config(os.getenv('FLASK_ENV', 'production')).
3. Assigns app.config['SECRET_KEY'] = config.SECRET_KEY.
4. Assigns app.config['DEBUG'] = config.DEBUG.
5. Assigns app.config['TESTING'] = config.TESTING.
6. Assigns app.config['SESSION_COOKIE_SECURE'] = config.SESSION_COOKIE_SECURE.
7. Assigns app.config['SESSION_COOKIE_HTTPONLY'] = config.SESSION_COOKIE_HTTPONLY.
8. Assigns app.config['SESSION_COOKIE_SAMESITE'] = config.SESSION_COOKIE_SAMESITE.
9. Assigns app.config['PERMANENT_SESSION_LIFETIME'] = config.PERMANENT_SESSION_LIFETIME.
10. Assigns app.config['MAX_CONTENT_LENGTH'] = config.MAX_CONTENT_LENGTH.
11. **return** app.

Code (copy-paste safe)

```
def configure_app(app):
    """Apply production-specific configurations."""
    from config.production import get_config

    config = get_config(os.getenv('FLASK_ENV', 'production'))

    # Apply configuration to app
    app.config['SECRET_KEY'] = config.SECRET_KEY
    app.config['DEBUG'] = config.DEBUG
```

```

app.config['TESTING'] = config.TESTING

# Session configuration
app.config['SESSION_COOKIE_SECURE'] = config.SESSION_COOKIE_SECURE
app.config['SESSION_COOKIE_HTTPONLY'] = config.SESSION_COOKIE_HTTPONLY
app.config['SESSION_COOKIE_SAMESITE'] = config.SESSION_COOKIE_SAMESITE
app.config['PERMANENT_SESSION_LIFETIME'] = config.PERMANENT_SESSION_LIFETIME

# File size limits
app.config['MAX_CONTENT_LENGTH'] = config.MAX_CONTENT_LENGTH

return app

```

Step 12.2 — Build gunicorn.conf.py

What to do. Create the file `gunicorn.conf.py` in your project root and paste in the code shown in this step. The file is **173** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

What this file is for. Gunicorn configuration. Worker counts, bind address, timeouts, and logging are read from variables at module scope.

`gunicorn.conf.py`

173 loc · 0 classes · 11 functions · 2 imports

Gunicorn configuration. Worker counts, bind address, timeouts, and logging are read from variables at module scope. It defines **11** module-level functions, across **173** lines. Module docstring: *Gunicorn Configuration for MT5 Hedging Dashboard*

Module docstring

```

Gunicorn Configuration for MT5 Hedging Dashboard
===== Production WSGI server configuration.

Usage: gunicorn -c gunicorn.conf.py wsgi:app

Or with custom settings: gunicorn --bind 0.0.0.0:8000 --workers 4 wsgi:app

```

Python concepts demonstrated in this module

- f-strings

Imports — what each one is for

```
import os
```

Why imported. Operating-system interface. Path manipulation, environment variables, working-directory operations, exit codes, and thin wrappers around POSIX/Windows syscalls.

Used in this file. `os.getenv`, `os.path`, `os.path.abspath`, `os.path.dirname`

Example. `os.path.join(root, 'subdir', 'file.txt')` # joins with the OS-correct separator

Other common scenarios.

- `os.environ.get('API_KEY')` to read environment variables
- `os.makedirs(path, exist_ok=True)` to create nested directories
- `os.listdir(path)` to list a directory's contents
- `os.remove(path)` / `os.rename(src, dst)` to delete or move a file
- `os.getcwd()` / `os.chdir(path)` to inspect or change the working dir

```
import multiprocessing
```

Why imported. *multiprocessing* — module specific to this codebase. See the chapter that covers its source for the full definition.

Used in this file. `multiprocessing.cpu_count`

Functions

```
def on_starting(server)
```

Called just before the master process is initialized.

Step by step (top-level body)

1. Calls `print(...)` for its side effect.

Code (copy-paste safe)

```
def on_starting(server):
    """Called just before the master process is initialized."""
    print("■ Starting MT5 Dashboard Gunicorn server...")
```

```
def on_reload(server)
```

Called before reloading the configuration.

Step by step (top-level body)

1. Calls `print(...)` for its side effect.

Code (copy-paste safe)

```
def on_reload(server):
    """Called before reloading the configuration."""
    print("■ Reloading MT5 Dashboard server configuration...")
```

```
def when_ready(server)
```

Called just after the server is started.

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Calls `print(...)` for its side effect.
2. Calls `print(...)` for its side effect.
3. Calls `print(...)` for its side effect.

Code (copy-paste safe)

```
def when_ready(server):
    """Called just after the server is started."""
    print(f"■ MT5 Dashboard server ready at {bind}")
    print(f"  Workers: {workers}")
    print(f"  Worker class: {worker_class}")
```

```
def worker_int(worker)
```

Called when a worker receives SIGINT or SIGQUIT.

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Calls `print(...)` for its side effect.

Code (copy-paste safe)

```
def worker_int(worker):
    """Called when a worker receives SIGINT or SIGQUIT."""
    print(f"■■ Worker {worker.pid} received interrupt signal")
```

```
def worker_abort(worker)
```

Called when a worker receives SIGABRT.

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Calls `print(...)` for its side effect.

Code (copy-paste safe)

```
def worker_abort(worker):
    """Called when a worker receives SIGABRT."""
    print(f"■ Worker {worker.pid} was aborted")
```

```
def pre_fork(server, worker)
```

Called just before a worker is forked.

Step by step (top-level body)

1. `pass` (placeholder).

Code (copy-paste safe)

```
def pre_fork(server, worker):  
    """Called just before a worker is forked."""  
    pass
```

```
def post_fork(server, worker)
```

Called just after a worker has been forked.

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Calls `print(...)` for its side effect.

Code (copy-paste safe)

```
def post_fork(server, worker):  
    """Called just after a worker has been forked."""  
    print(f"■ Worker {worker.pid} spawned")
```

```
def post_worker_init(worker)
```

Called just after a worker has initialized the application.

Step by step (top-level body)

1. `pass` (placeholder).

Code (copy-paste safe)

```
def post_worker_init(worker):  
    """Called just after a worker has initialized the application."""  
    pass
```

```
def worker_exit(server, worker)
```

Called just after a worker has been exited.

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Calls `print(...)` for its side effect.

Code (copy-paste safe)

```
def worker_exit(server, worker):  
    """Called just after a worker has been exited."""  
    print(f"■ Worker {worker.pid} exited")
```

```
def nworkers_changed(server, new_value, old_value)
```

Called when the number of workers has been changed.

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Calls `print(...)` for its side effect.

Code (copy-paste safe)

```
def nworkers_changed(server, new_value, old_value):
    """Called when the number of workers has been changed."""
    print(f"■ Workers changed: {old_value} → {new_value}")
```

```
def on_exit(server)
```

Called just before exiting Gunicorn.

Step by step (top-level body)

1. Calls `print(...)` for its side effect.

Code (copy-paste safe)

```
def on_exit(server):
    """Called just before exiting Gunicorn."""
    print("■ MT5 Dashboard server shutting down...")
```

Step 12.3 — Build build.py

What to do. Create the file `build.py` in your project root and paste in the code shown in this step. The file is **87** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

What this file is for. PyInstaller-driven build script. Packages the desktop trader companion into a Windows executable using one of the `.spec` files in the repo root.

build.py

87 loc · 0 classes · 1 functions · 4 imports

PyInstaller-driven build script. Packages the desktop trader companion into a Windows executable using one of the `.spec` files in the repo root. It defines **1** module-level function, across **87** lines.

Python concepts demonstrated in this module

- Context managers (with-statements)
- Exceptions
- f-strings

Imports — what each one is for

```
import os
```

Why imported. Operating-system interface. Path manipulation, environment variables, working-directory operations, exit codes, and thin wrappers around POSIX/Windows syscalls.

Used in this file. `os.path`, `os.path.abspath`, `os.path.dirname`, `os.path.exists`, `os.path.isdir`, `os.path.join`, `os.pathsep`

Example. `os.path.join(root, 'subdir', 'file.txt')` # joins with the OS-correct separator

Other common scenarios.

- `os.environ.get('API_KEY')` to read environment variables
- `os.makedirs(path, exist_ok=True)` to create nested directories
- `os.listdir(path)` to list a directory's contents
- `os.remove(path)` / `os.rename(src, dst)` to delete or move a file
- `os.getcwd()` / `os.chdir(path)` to inspect or change the working dir

```
import sys
```

Why imported. Access to the running interpreter — `argv`, `stdin/stdout`, exit codes, the import search path, and the platform name.

Used in this file. `sys.executable`, `sys.exit`

Example. `sys.exit(1)` # terminate the process with a non-zero status

Other common scenarios.

- `sys.argv[1:]` reads the command-line arguments
- `sys.path.insert(0, 'extra')` prepends to the import search path
- `sys.stderr.write(msg)` writes to standard error
- `sys.platform` tells you 'win32', 'linux', or 'darwin'
- `sys.modules` is the global cache of already-imported modules

```
import shutil
```

Why imported. High-level filesystem operations: copying trees, moving files across filesystems, deleting directories, locating executables on `PATH`.

Used in this file. `shutil.rmtree`

Example. `shutil.copytree(src, dst)` # recursively copies a tree

Other common scenarios.

- `shutil.move(src, dst)` moves or renames

- `shutil.rmtree(path)` deletes a directory and all its contents
- `shutil.which('git')` finds an executable on PATH
- `shutil.disk_usage(path)` returns total / used / free bytes

`import subprocess`

Why imported. Run external programs. The standard way to spawn a child process, capture its output, and wait for its exit code.

Used in this file. `subprocess.CalledProcessError`, `subprocess.run`

Example. `subprocess.run(['git', 'rev-parse', 'HEAD'], capture_output=True, text=True, check=True)`

Other common scenarios.

- `Popen(...)` for streaming I/O while the process is alive
- `check_output(cmd)` returns stdout as text and raises on failure
- `DEVNULL` / `PIPE` redirect stdin/stdout/stderr
- `shell=True` interprets the string with the system shell (security risk)

Module constants

Each line below is followed by a plain-English note explaining what it does and why it is written that way.

`PROJECT_ROOT = os.path.dirname(os.path.abspath(__file__))`

Filesystem path resolved relative to the source file at import time — portable across machines.

`TRADER_APP = os.path.join(PROJECT_ROOT, 'trader_companion', 'trader_app.py')`

Module-level constant — bound once at import time and referenced from the functions and classes below.

`LOGO_SRC = os.path.join(PROJECT_ROOT, 'trader_companion', 'logo.png')`

Module-level constant — bound once at import time and referenced from the functions and classes below.

`UTILS_SRC = os.path.join(PROJECT_ROOT, 'utils')`

Module-level constant — bound once at import time and referenced from the functions and classes below.

`TRADER_COMPANION_DIR = os.path.join(PROJECT_ROOT, 'trader_companion')`

Module-level constant — bound once at import time and referenced from the functions and classes below.

`DIST_DIR = os.path.join(PROJECT_ROOT, 'dist')`

Module-level constant — bound once at import time and referenced from the functions and classes below.

`BUILD_DIR = os.path.join(PROJECT_ROOT, 'build')`

Module-level constant — bound once at import time and referenced from the functions and classes below.

```
VERSION = get_version()
```

Module-level constant — bound once at import time and referenced from the functions and classes below.

```
BUILD_NAME = f'TradeopssAI_v{VERSION}'
```

Module-level constant — bound once at import time and referenced from the functions and classes below.

Functions

```
def get_version()
```

Extract version from trader_app.py

Why these Python concepts were used

- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. **with** open(TRADER_APP, 'r', encoding='utf-8'): enters a context manager.

2. **return** '1.0.0'.

Code (copy-paste safe)

```
def get_version():
    """Extract version from trader_app.py"""
    with open(TRADER_APP, 'r', encoding='utf-8') as f:
        for line in f:
            if line.strip().startswith('APP_VERSION'):
                return line.split('=')[1].strip().replace("'", '').replace('"', '')
    return '1.0.0'
```

Checkpoint — what works now. The project ships. `gunicorn -c gunicorn.conf.py wsgi:app` runs the dashboard in production-mode workers. `python build.py` packages the desktop companion into a Windows .exe. `python prepare_deployment.py` bundles the dashboard for upload to PythonAnywhere. The book ends here — you have built the platform.

Chapter 13 — The frontend: templates, CSS, and the JavaScript glue

Up to this point the book has been about Python — the request router, the database layer, the prop-firm integrations, the trader desktop app. This chapter is about the layer the user actually sees: Flask templates, the CSS that styles them, and the JavaScript embedded inside them. None of it is in a separate single-page-app: every page is server-rendered Jinja2, with progressive enhancement bolted on via inline `<script>` blocks.

That is a deliberate, slightly old-school choice. It means the dashboard works without a build step, a developer can read a page top to bottom without bouncing between framework files, and the same template that renders the page can also be the file you `grep` when something looks wrong. It costs us the SPA niceties (instant route changes, shared client state), but for a back-office dashboard the trade is fair.

How Flask templating works

Flask uses **Jinja2** as its templating engine. Three mustache-flavoured constructs do the heavy lifting:

- `{{ expression }}` — an *expression*: evaluate the Python expression inside the double braces and substitute the (HTML-escaped) result. This is how you print a variable.
- `{% statement %}` — a *statement*: control flow. `{% if user.is_admin %} ... {% endif %}`, `{% for client in clients %} ... {% endfor %}`, `{% extends 'base.html' %}`, `{% block title %}{% endblock %}`, `{% include 'sidebar.html' %}`.
- `{# comment #}` — a Jinja comment that is stripped before the HTML reaches the browser (unlike `<!-- ... -->`, which is sent and visible to anyone using View Source).

Inheritance is the trick that keeps things DRY. A parent template lays out the shell (header, nav, footer) and declares named `{% block %}` regions. Child templates do `{% extends 'parent.html' %}` and override only the blocks they care about. Read every *Inherits from* note below as: this child page reuses the parent's shell and only customises the named blocks.

Two helpers you will see referenced over and over:

- `url_for('endpoint_name')` — resolve a named Flask route into an actual URL at render time. Using this instead of hard-coding `/login` means moving a route is a one-line change in `app.py`, not a project-wide find-and-replace.
- `csrf_token()` — emits the CSRF token for forms protected by Flask-WTF. The server rejects POSTs where the token is missing or wrong; this is what blocks third-party sites from forging requests on behalf of a logged-in user.

All templates at a glance

Sorted by size. Use this as the chapter's table of contents — the bigger the template, the more of the user's actual experience lives inside it.

Template	LOC	Bytes	Forms	Scripts	Routes
index.html	8,748	477,009	0	1	1
super_admin.html	2,721	159,768	0	1	1
quality_dashboard.html	1,731	111,915	0	1	1
financial_overview.html	1,177	64,296	1	13	2
trader_dashboard.html	973	49,503	0	1	1
admin_dashboard.html	745	44,155	0	1	1
hierarchy.html	729	26,903	0	1	0
login.html	610	22,728	0	1	1
payout_history.html	554	27,968	1	4	2
client_performance.html	551	27,279	0	1	1
trader_performance.html	418	22,962	0	1	1
change_password.html	397	14,304	0	1	0
client_management.html	348	15,286	0	1	1
maintenance.html	259	8,388	0	1	0
500.html	250	8,312	0	0	0

Public & auth pages — what an unauthenticated visitor sees

These four templates are the only ones an unauthenticated or error-state user can reach. They are intentionally small and self-contained: when the rest of the app is broken, these are still expected to render.

dashboard/templates/login.html

610 loc · 22,728 bytes · 2 {{ ... }} expressions · 0 for loops · 0 if blocks

The sign-in screen. Reads email + password, posts to the login route, then redirects based on the user's role (admin / trader / client). Also renders password-reset prompts when applicable.

Standalone template — does not extend a parent. The full HTML document lives inside this single file.

Routes referenced via `url_for(...)`. static. Each entry is a Flask endpoint name — search for the matching `@app.route` or `@bp.route` decorator in `dashboard/app.py`.

UI libraries detected. Google Fonts. Loaded via either a `<script>` tag or a local static asset.

AJAX patterns detected. `fetch()`. The page is not purely server-rendered: parts of it talk back to Flask routes from the browser after the initial load.

Notes. 1 inline `<script>` block · 1 inline `<style>` block.

Opening of the template:

```
<!DOCTYPE html>
<html lang="en">
<head>
  <meta charset="UTF-8">
  <meta name="viewport" content="width=device-width, initial-scale=1.0">
  <title>Login - TradeOpss</title>
  <style>
    @import url(
      'https://fonts.googleapis.com/css2?family=Plus+Jakarta+Sans:wght@400;500;600;700;800;900&family=Space+Grotesk'
    );

    * { margin: 0; padding: 0; box-sizing: border-box; }

    body {
      font-family: 'Plus Jakarta Sans', 'Space Grotesk', -apple-system, sans-serif;
      height: 100vh;
      display: flex;
      flex-direction: column;
      align-items: center;
      justify-content: center;
      background-color: #01030a;
      background-image:
        radial-gradient(circle at 15% 50%, rgba(251,191,36,0.07) 0%, transparent 30%),
        radial-gradient(circle at 85% 20%, rgba(30,58,138,0.22) 0%, transparent 40%),
        radial-gradient(circle at 50% 100%, rgba(10,15,40,0.4) 0%, transparent 55%);
      background-attachment: fixed;
      color: #e8eeff;
      overflow: hidden;
      padding: 20px;
      position: relative;
    }
  </style>
</head>
```

dashboard/templates/change_password.html

397 loc · 14,304 bytes · 1 {{ ... }} expressions · 0 for loops · 0 if blocks

Forced password change after first login or admin reset. POSTs the new password and runs strength validation client-side before the server enforces it again.

Standalone template — does not extend a parent. The full HTML document lives inside this single file.

AJAX patterns detected. `fetch()`. The page is not purely server-rendered: parts of it talk back to Flask routes from the browser after the initial load.

Notes. 1 inline `<script>` block · 1 inline `<style>` block.

Opening of the template:

```
<!DOCTYPE html>
<html lang="en">
<head>
  <meta charset="UTF-8">
  <meta name="viewport" content="width=device-width, initial-scale=1.0">
  <title>Change Password - Trading Dashboard</title>
  <style>
    * { margin: 0; padding: 0; box-sizing: border-box; }

    body {
      font-family: -apple-system, BlinkMacSystemFont, 'Segoe UI', Roboto, Oxygen, Ubuntu, sans-serif;
      background: linear-gradient(135deg, #1a1a2e 0%, #16213e 50%, #0f3460 100%);
      min-height: 100vh;
      display: flex;
      justify-content: center;
      align-items: center;
      padding: 20px;
    }

    .container {
      background: rgba(255, 255, 255, 0.95);
      border-radius: 20px;
      box-shadow: 0 25px 50px rgba(0, 0, 0, 0.3);
      width: 100%;
      max-width: 420px;
      overflow: hidden;
    }

    .header {
      background: linear-gradient(135deg, #f59e0b 0%, #d97706 100%);
```

dashboard/templates/maintenance.html

259 loc · 8,388 bytes · 0 {{ ... }} expressions · 0 for loops · 0 if blocks

Maintenance-mode shield page. Served when the app is intentionally taken offline (during deploys, schema changes, or incident response).

Standalone template — does not extend a parent. The full HTML document lives inside this single file.

UI libraries detected. Google Fonts. Loaded via either a CDN `<script>` tag or a local static asset.

AJAX patterns detected. `fetch()`. The page is not purely server-rendered: parts of it talk back to Flask routes from the browser after the initial load.

Notes. 1 inline `<script>` block · 1 inline `<style>` block.

Opening of the template:

```
<!DOCTYPE html>
<html lang="en">
<head>
  <meta charset="UTF-8">
  <meta name="viewport" content="width=device-width, initial-scale=1.0">
  <title>Under Maintenance - TradeOps</title>
  <style>
    @import url(
      'https://fonts.googleapis.com/css2?family=Plus+Jakarta+Sans:wght@400;500;600;700;800;900&fam

    * { margin: 0; padding: 0; box-sizing: border-box; }

    body {
      font-family: 'Plus Jakarta Sans', 'Space Grotesk', -apple-system, sans-serif;
      height: 100vh;
      overflow: hidden;
      display: flex;
      align-items: center;
      justify-content: center;
      background-color: #01030a;
      background-image:
        radial-gradient(circle at 15% 50%, rgba(251,191,36,0.07) 0%, transparent 30%),
        radial-gradient(circle at 85% 20%, rgba(30,58,138,0.22) 0%, transparent 40%),
        radial-gradient(circle at 50% 100%, rgba(10,15,40,0.4) 0%, transparent 55%);
      background-attachment: fixed;
      color: #e8eeff;
      position: relative;
      padding: 20px;
    }

    body::before {
```

dashboard/templates/500.html

250 loc · 8,312 bytes · 0 {{ ... }} expressions · 0 for loops · 0 if blocks

Error page rendered for unhandled server errors. Deliberately minimal: when the rest of the app is on fire, this template must not require anything of it.

Standalone template — does not extend a parent. The full HTML document lives inside this single file.

UI libraries detected. Google Fonts. Loaded via either a CDN `<script>` tag or a local static asset.

Notes. 1 inline `<style>` block.

Opening of the template:

```
<!DOCTYPE html>
<html lang="en">
<head>
  <meta charset="UTF-8">
  <meta name="viewport" content="width=device-width, initial-scale=1.0">
  <title>Under Maintenance - TradeOps</title>
```

```

<style>
  @import url(
    'https://fonts.googleapis.com/css2?family=Plus+Jakarta+Sans:wght@400;500;600;700;800;900&fam

  * { margin: 0; padding: 0; box-sizing: border-box; }

  body {
    font-family: 'Plus Jakarta Sans', 'Space Grotesk', -apple-system, sans-serif;
    height: 100vh;
    overflow: hidden;
    display: flex;
    align-items: center;
    justify-content: center;
    background-color: #01030a;
    background-image:
      radial-gradient(circle at 15% 50%, rgba(251,191,36,0.07) 0%, transparent 30%),
      radial-gradient(circle at 85% 20%, rgba(30,58,138,0.22) 0%, transparent 40%),
      radial-gradient(circle at 50% 100%, rgba(10,15,40,0.4) 0%, transparent 55%);
    background-attachment: fixed;
    color: #e8eeff;
    position: relative;
    padding: 20px;
  }

  body::before {

```

Admin & super-admin views — the operations layer

These are the templates that the people running the desk spend their day inside. Heavier on tables, modals, and click-to-edit forms than on visualisations.

dashboard/templates/admin_dashboard.html

745 loc · 44,155 bytes · 5 {{ ... }} expressions · 0 for loops · 0 if blocks

Top-level admin landing page. Shows system-wide KPIs, the user hierarchy, and shortcuts to management tools. Lighter than super_admin.html — it is for day-to-day operators.

Standalone template — does not extend a parent. The full HTML document lives inside this single file.

Routes referenced via url_for(...). static. Each entry is a Flask endpoint name — search for the matching @app.route or @bp.route decorator in dashboard/app.py.

UI libraries detected. Font Awesome, Google Fonts. Loaded via either a CDN <script> tag or a local static asset.

AJAX patterns detected. fetch(). The page is not purely server-rendered: parts of it talk back to Flask routes from the browser after the initial load.

Notes. 1 inline <script> block · 1 inline <style> block.

Opening of the template:

```
<!DOCTYPE html>
<html lang="en">
<head>
  <meta charset="UTF-8">
  <meta name="viewport" content="width=device-width, initial-scale=1.0">
  <title>Admin Dashboard - TradeOpss</title>

      top: 12px;
      z-index: 500;
    }
    .nav-links { display: flex; gap: 4px; align-items: center; }
    .tab-btn {
      color: #7898be; text-decoration: none; font-weight: 600; font-size: 0.78rem;
    }
  </style>
</head>
```

dashboard/templates/super_admin.html

2,721 loc · 159,768 bytes · 4 {{ ... }} expressions · 0 for loops · 11 if blocks

Super-admin console. Adds operations (user CRUD, system-level toggles, deeper audit views) that ordinary admins cannot run. This is the second-largest template in the project.

Standalone template — does not extend a parent. The full HTML document lives inside this single file.

Routes referenced via `url_for(...)`. static. Each entry is a Flask endpoint name — search for the matching `@app.route` or `@bp.route` decorator in `dashboard/app.py`.

UI libraries detected. Font Awesome, Google Fonts. Loaded via either a CDN `<script>` tag or a local static asset.

AJAX patterns detected. `fetch()`. The page is not purely server-rendered: parts of it talk back to Flask routes from the browser after the initial load.

Notes. 1 inline `<script>` block · 1 inline `<style>` block.

Opening of the template:

```
<!DOCTYPE html>
<html lang="en">
<head>
  <meta charset="UTF-8">
  <meta name="viewport" content="width=device-width, initial-scale=1.0">

Other

The landing template. Despite the name, this file does not render the literal home URL — Flask routes pick which template to render based on the user's role. This is the fallback that holds the dashboard widgets shared across roles.

dashboard/templates/index.html

8,748 loc · 477,009 bytes · 22 {{ ... }} expressions · 0 for loops · 18 if blocks

The home/landing page after login. The largest template in the project — embeds the live dashboard widgets, charts, and most of the client-facing data tables. If you only read one template, read this one: it is where the 'shape' of the dashboard lives.

Standalone template — does not extend a parent. The full HTML document lives inside this single file.

Routes referenced via `url_for(...)`. static. Each entry is a Flask endpoint name — search for the matching `@app.route` or `@bp.route` decorator in `dashboard/app.py`.

UI libraries detected. Font Awesome, Google Fonts. Loaded via either a CDN `<script>` tag or a local static asset.

AJAX patterns detected. `fetch()`. The page is not purely server-rendered: parts of it talk back to Flask routes from the browser after the initial load.

Notes. 1 inline `<script>` block · 2 inline `<style>` blocks.

Opening of the template:

```
<!DOCTYPE html>
<html lang="en">
<head>
  <meta charset="UTF-8">
  <meta name="viewport" content="width=device-width, initial-scale=1.0">

```

The CSS layer

All custom styling lives in `dashboard/static/css/`. There is no preprocessor (Sass, Less) and no PostCSS pipeline — this is plain CSS, served as-is by Flask's static handler. That keeps the deploy story simple at the cost of a slightly longer single file.

`dashboard/static/css/style.css`

1,655 loc · 46,661 bytes · ~207 rules · 0 @media queries · 3 @keyframes animations · 32 CSS custom properties

A single concatenated stylesheet shared across every template. The inline `<style>` blocks in individual templates layer on top for page-specific tweaks. The 32 CSS custom properties (the `--name: value` declarations) are how the dashboard themes itself: change one variable at the `:root` level and every rule that references it updates.

Static HTML (no Flask, no Jinja)

A few HTML files live under `dashboard/static/` directly. These are served as plain files — Flask never templates them. Useful for pages that must render even when the Flask app itself is unreachable.

- `dashboard/static/maintenance.html`

How a request actually flows

Worth tracing in your head once. A user clicks a link to `/clients/42`. Unicorn (production) or Flask's dev server (local) accepts the TCP connection and hands it to `wsgi.py`, which exposes the Flask app object built in `dashboard/app.py`. Flask matches the URL against its registered routes, finds the handler, and calls it. The handler queries the database via SQLAlchemy, builds a context dictionary, and returns `render_template('client_performance.html', **context)`. Jinja loads the template, walks the `{% extends %}` chain, runs every `{{ expression }}` against the context, and produces the final HTML string. Flask wraps it in a 200 response and ships it back. The browser loads the inline JavaScript, which fires its own `fetch()` calls back to other Flask routes for the live charts. That last step is the only place where the two halves of the app meet asynchronously.

Chapter 14 — Glossary & concept index

Two reference tools. The glossary defines terms specific to this codebase — the trading domain it lives in, plus a few Python and framework names worth pinning down. The concept index maps every Python feature detected by the AST scanner to the modules that actually use it, so you can jump straight from a concept to a concrete working example.

Glossary

MT5 / MetaTrader 5

The retail-trader desktop platform from MetaQuotes. Exposes a Python API (the `MetaTrader5` package) that this codebase uses for order placement and history retrieval.

Prop firm

A proprietary trading firm that funds traders against an evaluation. Topstep, FundedNext, Tradovate, and TradeOpss are the four this codebase integrates with.

Funded account

An account a prop firm has cleared the trader to trade real capital on, after passing the evaluation challenge.

Hedging

Holding offsetting positions across linked accounts so that drawdown on one is bounded by gains on the other. The `hedge_protector` module implements this.

Watermark / high-water mark

The peak equity an account has reached. Payouts are calculated on profit above this watermark to prevent paying twice on the same gain.

Phase

An account's evaluation stage: challenge, verification, or funded. `phase_manager.py` owns the state machine.

Flask

Python micro-web-framework powering the dashboard. Routes are registered with the `@app.route` decorator.

SQLAlchemy

Python ORM. Database tables are declared as Python classes under `dashboard/models.py`.

Alembic

Migration framework that pairs with SQLAlchemy. Each file in `alembic/versions/` is a forward + rollback step.

APScheduler

Cron-style job scheduler used by dashboard/scheduler.py to run periodic resyncs.

Selenium / CDP

Browser-automation tooling. The prop-firm scrapers either drive a Chrome instance via Selenium or attach via the Chrome DevTools Protocol to read network traffic.

Tkinter

The standard-library GUI toolkit Python ships with. The trader companion's desktop window is built with it.

Gunicorn

Production WSGI server. Loads wsgi.py and runs the Flask app behind a worker pool.

Concept index

Each Python language feature, with the modules that use it. Concepts that appear in many modules are listed first; rarer ones at the end.

Exceptions (48 modules)

build.py, wsgi.py, trader_companion/fundednext.py, trader_companion/hedge_protector.py, trader_companion/mt5_comment_parser.py, trader_companion/mt5_dashboard_sync.py, trader_companion/mt5_trading.py, trader_companion/prop_firm_scrapers.py, trader_companion/push_data.py, trader_companion/signals/adx.py, trader_companion/signals/atr.py, trader_companion/signals/bb.py, trader_companion/signals/ccl.py, trader_companion/signals/dmi.py, trader_companion/signals/ema.py, trader_companion/signals/macd.py, trader_companion/signals/mfi.py, trader_companion/signals/momentum.py ... and 30 more
