

MT5HedgingEngine

Build a real Python trading platform from scratch — a step-by-step walkthrough of every file, every class, every function, with the actual source code inline.

This book teaches you to build the MT5HedgingEngine project end-to-end. We will create 72 Python files together — 50,959 lines of code, 59 classes (626 methods), and 468 module-level functions — in the dependency-correct order a working developer would build them.

Foreword — who this book is for

This book is for someone who knows a little Python — enough to open a REPL, write a function, and run a script — but has never built anything as large as a real trading platform. By the time you finish, you will have built one yourself, file by file, in the same order the original authors did, and you will understand why every line is the way it is.

The platform you will build does three things. First, it talks to MetaTrader 5 — a broker terminal — through MetaQuotes' official Python API: places orders, reads tick history, monitors open positions. Second, it scrapes prop-firm dashboards (Topstep, FundedNext, Tradovate, TradeOpss) using browser automation, because most prop firms have no public API. Third, it serves a Flask web dashboard where admins, managers and traders can see account state, payouts, and performance. A Tkinter desktop window ties the trader-side pieces together.

How the book is organised:

- **Chapter 1** walks you through getting a working Python development environment — installing Python, creating a virtual environment, the project folder layout, the requirements.txt file, the .env file, and the external pieces (MetaTrader 5 terminal, Chrome) you need on your machine.
- **Chapter 2** is a primer on the Python language features the rest of the book uses. Read it cover-to-cover or skim for unfamiliar names — you can come back to it whenever a later chapter mentions something you do not recognise.
- **Chapters 3 through 12** are the build itself, split into ten *phases*. Phase 1 is the boring foundation (settings, helpers); Phase 10 is the deployment scripts that ship the finished thing. Each phase opens with a one-page intro that tells you what you are about to build and why it comes next, then walks each file in order. Every class, every method, and every function gets four things: the source code itself, an explanation of which Python concepts it uses and why those were the right tools, a numbered step-by-step walkthrough of the body, and the function's own docstring where one exists.
- The **frontend chapter** picks up where the Python phases leave off and walks the user-facing layer: every Jinja template under dashboard/templates/, the static CSS under dashboard/static/, and the embedded JavaScript that gives each page its interactivity. Every template gets a stat block (LOC, expressions, forms, AJAX patterns), a one-line purpose, and the first ~30 lines of actual markup so you can read along.
- The **closing chapter** is a glossary plus a concept index — if you want to see real working examples of, say, decorators or generators or context managers, the index lists every module that uses each one.

How to use the book. Type the code in. Don't just read it. The whole point of building a project from scratch is that the muscle memory and the small surprises (a missing import, a typo in a config key, a mis-named column) are what teach you. The pages give you the destination; you take the steps. If something does not work, the right reaction is curiosity, not frustration — every error message is a piece of the language teaching you something specific.

Table of contents

Foreword — who this book is for

Chapter 1 — Project setup

Chapter 2 — Python concepts: a primer

- Modules and packages
- Classes and objects
- Inheritance
- Decorators
- Type hints
- Async / await
- Generators and yield
- Context managers (with-statements)
- Dataclasses
- Exceptions
- Comprehensions
- Properties
- f-strings
- Lambdas
- Dunder methods
- @classmethod and @staticmethod
- Module-level state

Chapter 3 — Phase 1 — Foundations: configuration and shared helpers

config/settings.py (32 loc, 0c, 0f)
config/production.py (145 loc, 4c, 1f)
config/hierarchy.py (452 loc, 0c, 24f)
utils/__init__.py (1 loc, 0c, 0f)
utils/data_processor.py (1349 loc, 0c, 14f)

Chapter 4 — Phase 2 — Persistence: the database layer

alembic/env.py (85 loc, 0c, 2f)
alembic/versions/44e368d8bfce_initial_schema.py (266 loc, 0c, 2f)
alembic/versions/5b29b54b57fa_add_firm_billing_column.py (31 loc, 0c, 2f)
dashboard/database.py (1940 loc, 2c, 90f)
dashboard/db.py (44 loc, 0c, 1f)
dashboard/models.py (330 loc, 18c, 0f)

Chapter 5 — Phase 3 — Talking to MetaTrader 5

connectors/mt5_connector.py (198 loc, 1c, 0f)
connectors/mt5_automator.py (2228 loc, 1c, 2f)

Chapter 6 — Phase 4 — Indicators and strategies

trader_companion/signals/__init__.py (2 loc, 0c, 0f)
trader_companion/signals/sma.py (27 loc, 0c, 1f)
trader_companion/signals/ema.py (27 loc, 0c, 1f)
trader_companion/signals/rsi.py (150 loc, 0c, 4f)
trader_companion/signals/macd.py (42 loc, 0c, 1f)
trader_companion/signals/bb.py (38 loc, 0c, 1f)
trader_companion/signals/atr.py (30 loc, 0c, 1f)
trader_companion/signals/adx.py (40 loc, 0c, 1f)
trader_companion/signals/dmi.py (42 loc, 0c, 1f)
trader_companion/signals/ccl.py (40 loc, 0c, 1f)
trader_companion/signals/momentum.py (33 loc, 0c, 1f)

trader_companion/signals/roc.py (33 loc, 0c, 1f)
trader_companion/signals/obv.py (35 loc, 0c, 1f)
trader_companion/signals/mfi.py (43 loc, 0c, 1f)
trader_companion/signals/stochastic.py (42 loc, 0c, 1f)
trader_companion/signals/supertrend.py (44 loc, 0c, 1f)
trader_companion/signals/sar.py (56 loc, 0c, 1f)
trader_companion/signals/tsi.py (39 loc, 0c, 1f)
trader_companion/signals/wr.py (38 loc, 0c, 1f)
trader_companion/signals/cmo.py (7 loc, 0c, 1f)
trader_companion/signals/coppock_curve.py (7 loc, 0c, 1f)
trader_companion/signals/donchian_channel.py (7 loc, 0c, 1f)
trader_companion/signals/elder_ray.py (7 loc, 0c, 1f)
trader_companion/signals/fractal.py (7 loc, 0c, 1f)
trader_companion/signals/gator_oscillator.py (7 loc, 0c, 1f)
trader_companion/signals/keltner_channel.py (7 loc, 0c, 1f)
trader_companion/signals/price_channel.py (7 loc, 0c, 1f)
trader_companion/signals/ultimate_oscillator.py (7 loc, 0c, 1f)
trader_companion/signals/vortex.py (7 loc, 0c, 1f)
trader_companion/strategies/__init__.py (2 loc, 0c, 0f)
trader_companion/strategies/rsi_overbought_oversold.py (22 loc, 0c, 1f)

Chapter 7 — Phase 5 — The trading engine

trader_companion/mt5_trading.py (2485 loc, 1c, 2f)
trader_companion/mt5_comment_parser.py (869 loc, 5c, 4f)
trader_companion/trade_limit_manager.py (388 loc, 2c, 4f)
trader_companion/hedge_protector.py (576 loc, 1c, 0f)

Chapter 8 — Phase 6 — Prop-firm dashboards

trader_companion/prop_firm_scrapers.py (1893 loc, 6c, 5f)
trader_companion/fundednext.py (1386 loc, 1c, 3f)
trader_companion/topstepx.py (4420 loc, 1c, 3f)
trader_companion/tradovate.py (3334 loc, 1c, 0f)
trader_companion/prop_firm_manager.py (2124 loc, 1c, 0f)

Chapter 9 — Phase 7 — Pushing data to the dashboard

trader_companion/push_data.py (194 loc, 0c, 4f)
trader_companion/mt5_dashboard_sync.py (840 loc, 1c, 1f)

Chapter 10 — Phase 8 — Desktop GUI

trader_companion/broker_selection.py (210 loc, 5c, 0f)
trader_companion/trader_app.py (8659 loc, 2c, 3f)

Chapter 11 — Phase 9 — Web dashboard

dashboard/email_service.py (260 loc, 0c, 4f)
dashboard/notes_service.py (76 loc, 0c, 3f)
dashboard/manage_api_keys.py (231 loc, 0c, 9f)
dashboard/api_client.py (201 loc, 1c, 0f)
dashboard/utils/sheet_helper.py (253 loc, 0c, 6f)
dashboard/utils/trade_matcher.py (361 loc, 1c, 0f)
dashboard/calc_like_sheet.py (111 loc, 0c, 3f)
dashboard/phase_manager.py (242 loc, 1c, 0f)
dashboard/watermark_service.py (688 loc, 0c, 22f)
dashboard/financial_overview.py (1718 loc, 1c, 24f)
dashboard/scheduler.py (605 loc, 0c, 12f)
dashboard/app.py (10470 loc, 2c, 172f)

Chapter 12 — Phase 10 — Deployment

wsgi.py (109 loc, 0c, 2f)

unicorn.conf.py (173 loc, 0c, 11f)
build.py (87 loc, 0c, 1f)

Chapter 13 — The frontend: templates, CSS, and the JavaScript glue

index.html (8,748 loc, 0 forms)
super_admin.html (2,721 loc, 0 forms)
quality_dashboard.html (1,731 loc, 0 forms)
financial_overview.html (1,177 loc, 1 form)
trader_dashboard.html (973 loc, 0 forms)
admin_dashboard.html (745 loc, 0 forms)
hierarchy.html (729 loc, 0 forms)
login.html (610 loc, 0 forms)
payout_history.html (554 loc, 1 form)
client_performance.html (551 loc, 0 forms)
trader_performance.html (418 loc, 0 forms)
change_password.html (397 loc, 0 forms)
client_management.html (348 loc, 0 forms)
maintenance.html (259 loc, 0 forms)
500.html (250 loc, 0 forms)

Chapter 14 — Glossary & concept index

Chapter 1 — Project setup

Before we write a single line of project code, we need a working development environment. This chapter is all setup — by the end of it you will have an empty project folder with Python, a virtual environment, the dependencies installed, and the external tools (MT5 terminal, Chrome) ready to go.

1.1 Install Python

Download Python 3.10 or newer from python.org/downloads. On Windows, tick the *Add Python to PATH* checkbox during install — without it, the `python` command will not be on your terminal's path. Verify the install by opening a fresh terminal and running:

```
python --version
```

You should see Python 3.10.x or newer. If you see 'python' is not recognised, the PATH did not get set — re-run the installer and tick the box, or add the Python folder to your PATH manually.

1.2 Create the project folder

Pick a place for the project and create the top-level folder. Everything we build lives inside this folder.

```
mkdir MT5HedgingEngine
cd MT5HedgingEngine
```

1.3 Create a virtual environment

A virtual environment is an isolated Python install that belongs to this project. It keeps the project's dependencies from clashing with anything else on your machine, and it is the single most useful habit a Python developer can have. Create and activate one:

```
python -m venv .venv
# Windows:
.venv\Scripts\activate
# macOS / Linux:
source .venv/bin/activate
```

After activation your terminal prompt should start with `(.venv)`. Every `pip` install from now on lands in this isolated environment, not in the system Python.

1.4 Create the folder layout

We will be building the following structure. Create the empty folders now — the files inside will be filled in chapter by chapter.

```
MT5HedgingEngine/
  config/
  utils/
  connectors/
  alembic/
  versions/
  trader_companion/
  signals/
  strategies/
```

```
utils/  
dashboard/  
utils/  
static/  
templates/
```

Python only treats a folder as an importable *package* when it contains an `__init__.py` file (it can be empty). For each of the folders above except `static/` and `templates/`, create an empty `__init__.py`:

```
# Windows PowerShell  
New-Item config/__init__.py, utils/__init__.py, connectors/__init__.py -ItemType File  
# macOS / Linux  
touch config/__init__.py utils/__init__.py connectors/__init__.py
```

1.5 Write requirements.txt

`requirements.txt` is the manifest of every third-party package the project depends on. Create it at the root with this content (the exact versions can be loosened later, but pinned versions reproduce the exact environment the original project ran on):

```
Flask  
Flask-Login  
Flask-Limiter  
SQLAlchemy  
alembic  
psycopg2-binary  
requests  
pandas  
numpy  
MetaTrader5  
selenium  
apscheduler  
python-dotenv  
werkzeug  
openpyxl  
pytz  
psutil  
websocket-client  
gunicorn  
reportlab
```

Install them all in one go (this will take a minute or two):

```
pip install -r requirements.txt
```

1.6 Create the .env file

Twelve-factor configuration says that anything that differs between dev and production should come from environment variables, not code. We use a `.env` file (loaded by `python-dotenv`) to keep those values out of git. Create `.env` in the project root with at least these keys:

```
FLASK_SECRET_KEY=change-me-to-a-long-random-string  
DATABASE_URL=sqlite:///dashboard.db  
MT5_LOGIN=  
MT5_PASSWORD=  
MT5_SERVER=  
GOOGLE_SHEETS_CREDS=  
SMTP_HOST=
```

```
SMTP_USER=  
SMTP_PASSWORD=
```

Add `.env` to your `.gitignore` **before** the first commit — it is going to hold real secrets later.

1.7 Install the MetaTrader 5 terminal

The MetaTrader5 Python package talks to a real terminal that has to be installed and logged in. Download it from your broker (or from *metatrader5.com*), install it, log in once with your account, and leave it running. The Python package on its own does nothing — it is a client to the terminal you just installed.

1.8 Install Chrome (for Selenium)

The prop-firm scrapers in Phase 6 drive a real Chrome browser. Install Chrome if you do not already have it. Modern Selenium ships with Selenium Manager, which downloads the matching chromedriver automatically — no extra install needed.

1.9 Verify the setup

Quick sanity check. From the project root, with the venv active, run:

```
python -c "import flask, sqlalchemy, pandas, MetaTrader5, selenium; print('OK')"
```

If you see OK, you are ready. If any of those imports fails, fix it before moving on — the rest of the book depends on them.

Chapter 2 — Python concepts: a primer

A short tour of the language features you will see across the rest of the book. Each section is brief by design — the goal is to give you a hook the real code can hang on. When a later chapter mentions a concept you do not remember, flip back here.

Modules and packages

Every `.py` file in Python is a *module*. A folder with an `__init__.py` file is a *package*. When you write from `trader_companion import mt5_trading`, Python finds the module file, executes it from top to bottom, and exposes the names defined inside (functions, classes, constants) under that module. Imports run only the first time — subsequent imports get the cached module object. This is why placing side-effect-heavy code at module scope is risky: it runs whenever the module is imported anywhere in the program.

Classes and objects

A class is a blueprint for objects. Calling the class — for example `Trade(symbol='EURUSD', volume=0.1)` — runs the special `__init__` method to construct an instance. Methods defined inside the class take `self` as their first parameter; Python passes the instance in automatically when you call `trade.close()`. Attributes set on `self` are per-instance; attributes set at class scope are shared across instances unless overridden.

Inheritance

A class can inherit from one (or many) base classes by listing them in parentheses: `class Topstep(PropFirm):`. The subclass gets every method and attribute from its parent for free, but can override any of them. `super().method()` calls the parent's version — useful when you want to extend behaviour rather than replace it. Inheritance is one form of code reuse; composition (holding another object as an attribute) is often simpler and more flexible.

Decorators

A decorator is a function that wraps another function (or class) to add behaviour. Writing `@app.route('/login')` above a function is shorthand for `login = app.route('/login')(login)`. Decorators are how Flask attaches URL handlers, how `@property` turns a method into an attribute lookup, and how `@staticmethod` tells Python that a method doesn't need `self`. Decorators stack: the one closest to the function runs first.

Type hints

Python is dynamically typed at runtime, but you can annotate parameters and returns: `def fetch(account: int) -> Trade:`. These annotations are not enforced — they exist for static checkers like `mypy/pyright`, IDE auto-complete, and human readers. The **typing** module supplies generics like `list[int]`, `Optional[str]`, and `dict[str, Any]`. From Python 3.10 onwards you can write `int | None` in place of `Optional[int]`.

Async / await

async def declares a coroutine — a function that returns an awaitable rather than a value. Inside it, **await** hands control back to the event loop while it waits for I/O. This lets a single thread juggle many slow operations (HTTP requests, websocket reads) concurrently without blocking. You launch coroutines with `asyncio.run(main())` or schedule them as tasks with `asyncio.create_task(coro)`.

Generators and yield

A function that uses **yield** instead of **return** becomes a generator: each call returns an iterator that produces values one at a time, on demand. This is how Python streams data without holding it all in memory. `for row in read_csv(path)` can iterate a million-row file lazily. `yield` from delegates to another iterator; combined with coroutines, generators were the foundation for `async/await`.

Context managers (with-statements)

with `open('file')` as `f`: guarantees that `f.close()` runs whether the block succeeds or raises. The object's `__enter__` runs at the start, `__exit__` at the end. Context managers express the acquire/release pattern: locks, database connections, transactions, temp files, MetaTrader-5 sessions. The `contextlib.contextmanager` decorator turns a generator into a context manager when you don't want to write the dunder methods by hand.

Dataclasses

A `@dataclass` auto-generates `__init__`, `__repr__`, and `__eq__` from the class's annotated fields. It removes the boilerplate from "plain data" objects. Use `field(default_factory=list)` for mutable defaults (never write `= []` at class scope — it leaks state across instances). `frozen=True` makes instances hashable and immutable.

Exceptions

Errors in Python travel up the call stack until something catches them. `try/except` catches; `raise` throws; `finally` runs cleanup regardless. Catch the narrowest exception you can — `except Exception` as the only handler will swallow `KeyboardInterrupt` on older code paths and hide real bugs. Define your own exception types by subclassing `Exception` when callers need to distinguish failure modes.

Comprehensions

`[x*2 for x in xs if x > 0]` builds a list in one expression. There are list, set, dict, and generator versions. Generator comprehensions use parentheses: `sum(x*2 for x in xs)` avoids materialising the intermediate list. Comprehensions are usually clearer than `map/filter` and faster than the equivalent `for-loop` because the list is sized once.

Properties

`@property` turns a method into an attribute lookup. `account.equity` can run a calculation each time it is accessed without exposing the call syntax. A matching `@equity.setter` lets you intercept assignment. Properties are how you migrate a public attribute to a computed value without breaking callers.

f-strings

`f'Account {a.id} balance ${a.balance:,.2f}'` is Python's modern interpolation syntax. The format spec after the colon (`,.2f`, `%`, `:<20`) controls width, precision, and alignment. f-strings are compiled into the bytecode at parse time, so they are also the fastest formatting option.

Lambdas

A **lambda** is a single-expression anonymous function. `sorted(trades, key=lambda t: t.profit)` avoids naming a one-line helper. Anything more than a single expression should be a regular `def` — lambdas lose statements, type hints, and a useful traceback name.

Dunder methods

Methods with double-underscore names (`__init__`, `__repr__`, `__eq__`, `__len__`) hook into Python's syntax. Defining `__len__` makes `len(obj)` work; `__iter__` makes it usable in `for`; `__getitem__` enables `obj[key]`. They are how user-defined classes behave like built-in types.

@classmethod and @staticmethod

`@classmethod` receives the class itself as its first argument (`cls` by convention). It is the standard way to define alternate constructors: `Trade.from_mt5_order(...)`. `@staticmethod` takes neither `self` nor `cls` — use it when a function logically belongs to the class's namespace but doesn't need access to any state.

Module-level state

Variables assigned at module top-level are global to that module. They are convenient for caches and singletons, but they can make testing harder because every import shares the same instance. Prefer passing values explicitly; reach for module-level state only when there is genuinely one of something (a database engine, a logger).

Chapter 3 — Phase 1 — Foundations: configuration and shared helpers

Every project starts with the boring-but-essential plumbing: a place for settings (the values that change between dev and production), and a small kit of helpers shared by everything else. We build these first because every later phase imports them. If you have not yet created a `config/` and `utils/` folder under your project root, do that now — Python only treats a folder as a package when it contains an `__init__.py` file, even an empty one.

Files we build in this phase, in order:

- `config/settings.py`
- `config/production.py`
- `config/hierarchy.py`
- `utils/__init__.py`
- `utils/data_processor.py`

Python concepts you'll meet in this phase

• f-strings (2) · Module-level state (2) · Context managers (with-statements) (2) · Comprehensions (2) · Exceptions (2) · Properties (1) · Classes and objects (1) · Decorators (1)

Each is explained in Chapter 2 (the primer). The number in parentheses is how many of this phase's files use that concept.

Step 3.1 — Build `config/settings.py`

What to do. Create the file `config/settings.py` in your project root and paste in the code shown in this step. The file is **32** lines long; we walk through it piece by piece below.

Depends on. This file imports from internal modules built in earlier steps: `config`. If any of those imports fail, jump back to the step that introduced them.

What this file is for. Centralised configuration. Reads from environment variables with sensible local-development defaults.

`config/settings.py`

32 loc · 0 classes · 0 functions · 2 imports

Centralised configuration. Reads from environment variables with sensible local-development defaults. across **32** lines.

Imports — what each one is for

```
import os
```

Why imported. Operating-system interface. Path manipulation, environment variables, working-directory operations, exit codes, and thin wrappers around POSIX/Windows syscalls.

Used in this file. `os.getenv`

Example. `os.path.join(root, 'subdir', 'file.txt')` # joins with the OS-correct separator

Other common scenarios.

- `os.environ.get('API_KEY')` to read environment variables
- `os.makedirs(path, exist_ok=True)` to create nested directories
- `os.listdir(path)` to list a directory's contents
- `os.remove(path)` / `os.rename(src, dst)` to delete or move a file
- `os.getcwd()` / `os.chdir(path)` to inspect or change the working dir

```
from config.hierarchy import get_client_profile
```

Why imported. Internal package — application settings and the firm hierarchy.

Used in this file. `get_client_profile`

Module constants

Each line below is followed by a plain-English note explaining what it does and why it is written that way.

```
CLIENT_NAME = os.getenv('CLIENT_NAME', 'Chris')
```

Reads `CLIENT_NAME` from the environment, defaulting to 'Chris' when not set — overridable per environment without a code change.

```
MT5_LOGIN = int(os.getenv('MT5_LOGIN', 3053752))
```

Reads `MT5_LOGIN` from the environment and converts it to int (env vars are always strings). Falls back to 3053752 when unset.

```
MT5_PASSWORD = os.getenv('MT5_PASSWORD', 'Blueedge1!')
```

Reads `MT5_PASSWORD` from the environment, defaulting to 'Blueedge1!' when not set — overridable per environment without a code change.

```
MT5_SERVER = os.getenv('MT5_SERVER', 'PlexyTrade-Server01')
```

Reads `MT5_SERVER` from the environment, defaulting to 'PlexyTrade-Server01' when not set — overridable per environment without a code change.

```
MT5_TERMINAL = os.getenv('MT5_TERMINAL', 'MetaTrader 5 (MetaTrader 5)')
```

Reads `MT5_TERMINAL` from the environment, defaulting to 'MetaTrader 5 (MetaTrader 5)' when not set — overridable per environment without a code change.

```
MT5_SYMBOL = os.getenv('MT5_SYMBOL', 'USTECH')
```

Reads MT5_SYMBOL from the environment, defaulting to 'USTECH' when not set — overridable per environment without a code change.

```
SHEET_URL = 'https://docs.google.com/spreadsheets/d/1vtuGcTe8ys44wHCJGJr6VoImeh8q0beaKkZMt0hd3VU/edit?usp=
```

URL constant pointing to an external resource. Hard-coded at load time; change here, not in callers.

```
ENABLE_GPT5_MINI = os.getenv('ENABLE_GPT5_MINI', 'true').lower() == 'true'
```

Boolean feature flag. Reads ENABLE_GPT5_MINI from the environment, lowercases it, and compares to 'true' — producing a real Python bool. Defaults to 'true'.

Step 3.2 — Build config/production.py

What to do. Create the file config/production.py in your project root and paste in the code shown in this step. The file is **145** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from requirements.txt.

What this file is for. Production-only overrides for settings.py.

config/production.py

145 loc · 4 classes · 1 functions · 2 imports

Production-only overrides for settings.py. It defines **4** classes and **1** module-level function, across **145** lines. Module docstring: *Production Configuration for MT5 Hedging Dashboard*

Module docstring

Production Configuration for MT5 Hedging Dashboard

===== This module provides
environment-specific configurations. Use environment variables to override settings in production.

Python concepts demonstrated in this module

• Classes and objects • Decorators • f-strings • Inheritance • Properties

Imports — what each one is for

```
import os
```

Why imported. Operating-system interface. Path manipulation, environment variables, working-directory operations, exit codes, and thin wrappers around POSIX/Windows syscalls.

Used in this file. os.getenv

Example. os.path.join(root, 'subdir', 'file.txt') # joins with the OS-correct separator

Other common scenarios.

- os.environ.get('API_KEY') to read environment variables

- `os.makedirs(path, exist_ok=True)` to create nested directories
- `os.listdir(path)` to list a directory's contents
- `os.remove(path)` / `os.rename(src, dst)` to delete or move a file
- `os.getcwd()` / `os.chdir(path)` to inspect or change the working dir

```
from datetime import timedelta
```

Why imported. Dates, times, durations. The fundamental temporal types: date, time, datetime, timedelta, timezone.

Used in this file. timedelta

Example. `datetime.now() - timedelta(days=7)` # one week ago

Other common scenarios.

- `datetime.strptime(s, '%Y-%m-%d')` parses a string
- `datetime.strftime(fmt)` formats one
- `datetime.fromtimestamp(n)` converts a Unix epoch
- `datetime.utcnow()` for UTC (better: `datetime.now(timezone.utc)`)

Classes

```
class Config
```

Base configuration class.

```
SECRET_KEY = os.getenv('FLASK_SECRET_KEY', 'change-this-in-production')
DEBUG = False
TESTING = False
APP_NAME = 'MT5 Hedging Dashboard'
APP_VERSION = '1.0.1'

```

Method: Config.DATABASE_URL

```

@property
def DATABASE_URL(self)

```

Generate database URL based on configuration.

Why these Python concepts were used

- **@property** — Wrapped in **@property** so callers access the value with attribute syntax (obj.x) instead of a method call. Lets the implementation compute or validate the value lazily without changing the call site.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **if self.DATABASE_TYPE == 'postgresql':** branches conditionally.

2. `return f'sqlite:///{self.SQLITE_PATH}'`.

Code (copy-paste safe)

```
def DATABASE_URL(self):
    """Generate database URL based on configuration."""
    if self.DATABASE_TYPE == 'postgresql':
        return f"postgresql://{self.POSTGRES_USER}:{self.POSTGRES_PASSWORD}@{self.POSTGRES_HOST}:{self.POSTGRES_PORT}"
    return f"sqlite:///self.SQLITE_PATH"
```

```
class DevelopmentConfig(Config)
```

Development configuration.

```
DEBUG = True
SESSION_COOKIE_SECURE = False
DATABASE_TYPE = 'sqlite'
RATELIMIT_STORAGE_URL = 'memory://'
CACHE_TYPE = 'simple'
LOG_LEVEL = 'DEBUG'
```

Code (copy-paste safe)

```

    EMAIL_ENABLED = False
```

Functions

```
def get_config(env=None)

    Get configuration based on environment.
```

Step by step (top-level body)

1. **if** env is None: branches conditionally.
2. **return** config.get(env, config['default'])().

Code (copy-paste safe)

```
def get_config(env=None):
    """Get configuration based on environment."""
    if env is None:
        env = os.getenv('FLASK_ENV', 'development')
    return config.get(env, config['default'])()
```

Step 3.3 — Build config/hierarchy.py

What to do. Create the file config/hierarchy.py in your project root and paste in the code shown in this step. The file is **452** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from requirements.txt.

What this file is for. Loads and validates the firm hierarchy (admin / manager / trader) tree out of hierarchy.json.

config/hierarchy.py

452 loc · 0 classes · 24 functions · 2 imports

Loads and validates the firm hierarchy (admin / manager / trader) tree out of hierarchy.json. It defines **24** module-level functions, across **452** lines.

Python concepts demonstrated in this module

• Comprehensions • Context managers (with-statements) • Exceptions • Module-level state

Imports — what each one is for

```
import json
```

Why imported. JSON encoding and decoding — the standard wire format for config files, API payloads, and inter-process messages.

Used in this file. json.dump, json.load

Example. json.loads(response.text) # parse a JSON string to dict

Other common scenarios.

- json.dumps(obj, indent=2) for pretty-printing
- json.dump(obj, file) / json.load(file) for file I/O
- default=str handles non-serialisable types like datetime
- object_hook= customises decoding (e.g., to dataclass instances)

```
import os
```

Why imported. Operating-system interface. Path manipulation, environment variables, working-directory operations, exit codes, and thin wrappers around POSIX/Windows syscalls.

Used in this file. os.makedirs, os.path, os.path.dirname, os.path.exists, os.path.join

Example. os.path.join(root, 'subdir', 'file.txt') # joins with the OS-correct separator

Other common scenarios.

- os.environ.get('API_KEY') to read environment variables
- os.makedirs(path, exist_ok=True) to create nested directories
- os.listdir(path) to list a directory's contents
- os.remove(path) / os.rename(src, dst) to delete or move a file
- os.getcwd() / os.chdir(path) to inspect or change the working dir

Module constants

Each line below is followed by a plain-English note explaining what it does and why it is written that way.

```
BASE_DIR = os.path.dirname(__file__)
```

Filesystem path resolved relative to the source file at import time — portable across machines.

```
RESTRUCTURED_FILE = os.path.join(BASE_DIR, 'hierarchy_restructured.json')
```

Module-level constant — bound once at import time and referenced from the functions and classes below.

```
LEGACY_FILE = os.path.join(BASE_DIR, 'hierarchy.json')
```

Module-level constant — bound once at import time and referenced from the functions and classes below.

```
HIERARCHY_FILE = RESTRUCTURED_FILE if os.path.exists(RESTRUCTURED_FILE) else LEGACY_FILE
```

Module-level constant — bound once at import time and referenced from the functions and classes below.

```
SYSTEM_HIERARCHY = load_hierarchy()
```

Module-level constant — bound once at import time and referenced from the functions and classes below.

Functions

```
def load_hierarchy():
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **dict comprehension** — Builds a dict in one expression (`{k: v for k, v in items}`) — same intent as a list comprehension but for mappings.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. `if os.path.exists(HIERARCHY_FILE):` branches conditionally.
2. `return {'admins': {}}.`

Code (copy-paste safe)

```
def load_hierarchy():
    if os.path.exists(HIERARCHY_FILE):
        with open(HIERARCHY_FILE, "r", encoding="utf-8") as f:
            data = json.load(f)

        # Compatibility: if the file is the "restructured" shape (admins -> clients + top-level traders)
        # convert it in-memory to the legacy nested shape {admins: {admin: {traders: {trader: {clients: ...}}}}
        try:
            if isinstance(data, dict) and 'admins' in data:
```

```

sample_admin = next(iter(data['admins'].values())) if data['admins'] else None
# Restructured format: admin entries contain 'clients' (list) and there is a top-level 't
if sample_admin is not None and 'clients' in sample_admin and 'traders' not in sample_admin:
    trader_registry = data.get('traders', {}) if isinstance(data.get('traders', {}),
    dict) else {}
    new_admins = {}
    for admin_name, admin_data in data.get('admins', {}).items():
        traders_map = {}
        for client in admin_data.get('clients', []):
            assigned = (client.get('assigned_trader') or '').strip()
            # Use assigned trader as key; if missing, group under empty-string key
            key = assigned
            if key not in traders_map:
                tr_email = trader_registry.get(key, {}).get('email', '') if key else ''
                traders_map[key] = {'email': tr_email, 'clients': []}
            # Keep assigned_trader on the client object for frontend/UI use
            client_copy = dict(client)
            traders_map[key]['clients'].append(client_copy)
        # Preserve all original admin fields (email, slack_user_id, etc.)
        preserved = {k: v for k, v in admin_data.items() if k != 'clients'}
        preserved['traders'] = traders_map
        new_admins[admin_name] = preserved
    data['admins'] = new_admins
except Exception:
    # If conversion fails for any reason, fall back to raw data
    pass

return data

return {"admins": {}}
```

```
def reload_hierarchy()
```

Reloads the hierarchy from disk to ensure freshness.

Why these Python concepts were used

- **global** — Rebinds a module-level name from inside the function. A smell in larger codebases — usually means a singleton or cache that could be passed in instead.

Step by step (top-level body)

1. Declares globals: SYSTEM_HIERARCHY.
2. Assigns new_data = load_hierarchy().
3. Calls SYSTEM_HIERARCHY.clear(...) for its side effect.
4. Calls SYSTEM_HIERARCHY.update(...) for its side effect.
5. **return** SYSTEM_HIERARCHY.

Code (copy-paste safe)

```

def reload_hierarchy():
    """Reloads the hierarchy from disk to ensure freshness."""
    global SYSTEM_HIERARCHY
    new_data = load_hierarchy()
    SYSTEM_HIERARCHY.clear()
    SYSTEM_HIERARCHY.update(new_data)
    return SYSTEM_HIERARCHY
```

```
def _to_flat_format(hierarchy_data)
```

Convert in-memory nested format back to flat format for disk persistence.

Why these Python concepts were used

- **dict comprehension** — Builds a dict in one expression (`{k: v for k, v in items}`) — same intent as a list comprehension but for mappings.

Step by step (top-level body)

1. Imports copy (lazy import inside the function).
2. Assigns `out = copy.deepcopy(hierarchy_data)`.
3. **for** `(admin_name, admin_data) in out.get('admins', {}).items():` iterates.
4. **return** out.

Code (copy-paste safe)

```
def _to_flat_format(hierarchy_data):
    """Convert in-memory nested format back to flat format for disk persistence."""
    import copy
    out = copy.deepcopy(hierarchy_data)
    for admin_name, admin_data in out.get('admins', {}).items():
        if 'traders' in admin_data and 'clients' not in admin_data:
            flat_clients = []
            for trader_name, trader_data in admin_data['traders'].items():
                for client in trader_data.get('clients', []):
                    c = dict(client)
                    c['assigned_trader'] = trader_name
                    flat_clients.append(c)
            # Preserve non-traders keys (email, slack_user_id, etc.)
            preserved = {k: v for k, v in admin_data.items() if k != 'traders'}
            out['admins'][admin_name] = {**preserved, 'clients': flat_clients}
    return out
```

```
def save_hierarchy(hierarchy_data)
```

Why these Python concepts were used

- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. Calls `os.makedirs(...)` for its side effect.
2. Assigns `flat = _to_flat_format(hierarchy_data)`.
3. **with** `open(HIERARCHY_FILE, 'w')`: enters a context manager.
4. **if** `hierarchy_data` is not `SYSTEM_HIERARCHY`: branches conditionally.

Code (copy-paste safe)

```
def save_hierarchy(hierarchy_data):
    # Ensure directory exists
    os.makedirs(os.path.dirname(HIERARCHY_FILE), exist_ok=True)
    # Always persist in flat format so the JSON structure stays consistent
```

```

flat = _to_flat_format(hierarchy_data)
with open(HIERARCHY_FILE, "w") as f:
    json.dump(flat, f, indent=4)

# Also update in-memory reference immediately
if hierarchy_data is not SYSTEM_HIERARCHY:
    SYSTEM_HIERARCHY.clear()
    SYSTEM_HIERARCHY.update(hierarchy_data)

def reassign_client_trader(client_name, admin_name, new_trader)

    Reassign a client to a different trader within the same admin. Auto-creates the new trader lane under the admin if it doesn't exist, pulling the email from the top-level traders registry. Returns True on success, False if the client or admin cannot be found.

```

Why these Python concepts were used

- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.

Step by step (top-level body)

1. Calls `reload_hierarchy(...)` for its side effect.
2. Assigns `admins = SYSTEM_HIERARCHY.get('admins', {})`.
3. **if** `admin_name` not in `admins`: branches conditionally.
4. Assigns `found_admin = None`.
5. Assigns `old_trader = None`.
6. **for** `search_admin` in `[admin_name] + [a for a in admins if a != admin_name]`: iterates.
7. **if** `old_trader` is `None` or `found_admin` is `None`: branches conditionally.
8. **if** `old_trader == new_trader` and `found_admin == admin_name`: branches conditionally.
9. Assigns `source_traders = admins[found_admin].get('traders', {})`.
10. Assigns `target_traders = admins[admin_name].get('traders', {})`.
11. **if** `new_trader` not in `target_traders`: branches conditionally.
12. Assigns `old_clients = source_traders[old_trader]['clients']`.
13. Assigns `client_obj = None`.
14. **for** `(i, c)` in `enumerate(old_clients)`: iterates.
15. ... and 6 more statement(s) in the body.

Code (copy-paste safe)

```

def reassign_client_trader(client_name, admin_name, new_trader):
    """
    Reassign a client to a different trader within the same admin.
    Auto-creates the new trader lane under the admin if it doesn't exist,
    pulling the email from the top-level traders registry.
    Returns True on success, False if the client or admin cannot be found.
    """
    reload_hierarchy()

```

def move_client(client_name, old_admin, old_trader, new_admin, new_trader)
```

Why these Python concepts were used

- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to `sum`, `any`, `all`, or `max` where the intermediate list would be wasted.

Step by step (top-level body)

1. **if** `old_admin` not in `SYSTEM_HIERARCHY['admins']`: branches conditionally.
2. **if** `old_trader` not in `SYSTEM_HIERARCHY['admins'][old_admin]['traders']`: branches conditionally.
3. **if** `new_admin` not in `SYSTEM_HIERARCHY['admins']`: branches conditionally.

4. if new_trader not in SYSTEM_HIERARCHY['admins'][new_admin]['traders']: branches conditionally.
5. Assigns old_clients = SYSTEM_HIERARCHY['admins'][old_admin]['traders'][old_trad....
6. Assigns client_data = None.
7. Assigns client_index = -1.
8. for (i, c) in enumerate(old_clients): iterates.
9. if client_data is None: branches conditionally.
10. Assigns new_clients = SYSTEM_HIERARCHY['admins'][new_admin]['traders'][new_trad....
11. if any((c['name'] == client_name for c in new_clients)): branches conditionally.
12. Delete statement.
13. Calls new_clients.append(...) for its side effect.
14. Calls save_hierarchy(...) for its side effect.
15. ... and 1 more statement(s) in the body.

Code (copy-paste safe)

```
def move_client(client_name, old_admin, old_trader, new_admin, new_trader):

                "must_change_password": 0,
                "is_active": 1
            }

    return None
```

Step 3.4 — Build `utils/__init__.py`

What to do. Create the file `utils/__init__.py` in your project root and paste in the code shown in this step. The file is **1** line long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

utils/__init__.py

1 loc · 0 classes · 0 functions · 0 imports

Package marker. Importing this folder as a module runs the code here (often empty, sometimes used to re-export public names). across **1** lines.

Step 3.5 — Build `utils/data_processor.py`

What to do. Create the file `utils/data_processor.py` in your project root and paste in the code shown in this step. The file is **1349** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

What this file is for. Generic dataframe helpers — date normalisation, currency parsing, signed-number coercion.

utils/data_processor.py

1349 loc · 0 classes · 14 functions · 8 imports

Generic dataframe helpers — date normalisation, currency parsing, signed-number coercion. It defines **14** module-level functions, across **1,349** lines.

Python concepts demonstrated in this module

• Comprehensions • Context managers (with-statements) • Exceptions • f-strings •
Module-level state • Lambdas

Imports — what each one is for

```
from collections import defaultdict
```

Why imported. Specialised container datatypes that the dict / list / tuple / set primitives don't cover.

Used in this file. `defaultdict`

Example. `Counter(words)` # multiset that counts occurrences

Other common scenarios.

- `defaultdict(list)` auto-creates a default value on missing keys
- `deque(maxlen=N)` is a double-ended bounded queue

- OrderedDict (mostly redundant since 3.7 — dicts preserve order)
- namedtuple('Point', 'x y') for tiny immutable record types

```
from datetime import datetime
from datetime import date
from datetime import time
```

Why imported. Dates, times, durations. The fundamental temporal types: date, time, datetime, timedelta, timezone.

Used in this file. datetime

Example. datetime.now() - timedelta(days=7) # one week ago

Other common scenarios.

- datetime.strptime(s, '%Y-%m-%d') parses a string
- datetime.strftime(fmt) formats one
- datetime.fromtimestamp(n) converts a Unix epoch
- datetime.utcnow() for UTC (better: datetime.now(timezone.utc))

```
import pandas as pd
```

Why imported. DataFrame library — the workhorse for tabular data: loading CSV/Excel/SQL, joins, aggregations, time-series.

Used in this file. pd.isna, pd.read_csv, pd.to_datetime

Example. df = pd.read_csv(path); df.groupby('symbol')['pnl'].sum()

Other common scenarios.

- df.merge(other, on='key') joins like SQL
- df.resample('1D').agg(...) for time-series rebucketing
- df.to_sql / df.to_excel / df.to_parquet for output
- df.loc[mask, 'col'] for label-based selection/assignment

```
import requests
```

Why imported. The de-facto Python HTTP client. Synchronous; trades raw speed for an extremely friendly API.

Used in this file. requests.get

Example. requests.get(url, timeout=10).json()

Other common scenarios.

- Session() reuses TCP connections across calls
- params=, headers=, json=, data= for query/body shapes
- raise_for_status() turns 4xx/5xx into an exception
- stream=True for large downloads

```
from io import StringIO
```

Why imported. In-memory streams and the abstract base classes for file objects. Useful when an API expects a file but you only have bytes/text in memory.

Used in this file. StringIO

Example. io.BytesIO(b'data') # behaves like an open binary file

Other common scenarios.

- io.StringIO('text') for an in-memory text stream
- io.TextIOWrapper wraps a binary stream with an encoding

```
import io
```

Why imported. In-memory streams and the abstract base classes for file objects. Useful when an API expects a file but you only have bytes/text in memory.

Used in this file. io.BytesIO

Example. io.BytesIO(b'data') # behaves like an open binary file

Other common scenarios.

- io.StringIO('text') for an in-memory text stream
- io.TextIOWrapper wraps a binary stream with an encoding

```
import math
```

Why imported. Math functions — log, sqrt, trig, constants. Pure scalar operations (vectorised math lives in numpy).

Used in this file. math.isinf, math.isnan

Example. math.sqrt(x*x + y*y)

Other common scenarios.

- math.inf / math.nan / math.pi / math.e
- math.isnan(x), math.isinf(x) for predicates
- math.floor(x), math.ceil(x), math.trunc(x) for rounding

```
import re
```

Why imported. Regular expressions. Pattern matching, search, replace, and text extraction.

Used in this file. re.IGNORECASE, re.escape, re.findall, re.finditer, re.match, re.search, re.sub

Example. re.search(r'\d{3}-\d{4}', text) # returns a Match or None

Other common scenarios.

- re.findall(pattern, text) for every non-overlapping match
- re.sub(pattern, repl, text) to replace occurrences
- re.compile(...) to reuse a pattern (faster in a loop)
- Named groups: r'(?P<year>\d{4})' lets you do m.group('year')

Module constants

Each line below is followed by a plain-English note explaining what it does and why it is written that way.

```
_FIRM_MAP = {'mffu': 'My Funded Futures', 'mffuflex': 'My Funded Futures',  
            'myfundedfutures': 'My Funded Futures', 'myfundedfx': 'My Funded Futures', ...
```

Mapping or set literal — a lookup table referenced elsewhere in the module.

Functions

```
def clean_float(val)
```

Ensures float values are JSON compliant (no NaN or Inf). Returns 0.0 if invalid.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def clean_float(val):  
    """  
    Ensures float values are JSON compliant (no NaN or Inf).  
    Returns 0.0 if invalid.  
    """  
    try:  
        f_val = float(val)  
        if math.isnan(f_val) or math.isinf(f_val):  
            return 0.0  
        return f_val  
    except:  
        return 0.0
```

```
def normalize_prop_firm(name)
```

Normalize prop firm name to canonical form to prevent duplicates.

Step by step (top-level body)

1. **if** not name: branches conditionally.
2. Assigns original = str(name).strip().
3. Assigns key = original.lower().replace(' ', '').replace('_', '').
4. **if** key in _FIRM_MAP: branches conditionally.
5. **if** 'myfundedfutures' in key or 'myfundedfx' in key: branches conditionally.
6. **if** 'fundednext' in key: branches conditionally.
7. **if** 'topstep' in key: branches conditionally.
8. **if** 'fundingtick' in key: branches conditionally.
9. **return** original.

Code (copy-paste safe)

```
def normalize_prop_firm(name):
    """Normalize prop firm name to canonical form to prevent duplicates."""
    if not name:
        return "Unknown"
    original = str(name).strip()
    key = original.lower().replace(" ", "").replace("-", "")
    if key in _FIRM_MAP:
        return _FIRM_MAP[key]
    # Partial matches for common patterns
    if "myfundedfutures" in key or "myfundedfx" in key:
        return "My Funded Futures"
    if "fundednext" in key:
        return "FundedNext"
    if "topstep" in key:
        return "Topstep"
    if "fundingtick" in key:
        return "Funding Ticks"
    return original

def normalize_account_size(value)

    Normalize account size values to standard format: $X,XXX (v1.0.1) Handles: - "50k", "50K" → "$50,000"
    - "100000", "100,000" → "$100,000" - "$50,000" → "$50,000" (already correct) - "5000" → "$5,000"
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **if** not value: branches conditionally.
2. Assigns `val = str(value).strip().upper()`.
3. **if** `re.match('^\\$[\\d,]+$', val)`: branches conditionally.
4. Assigns `match = re.match('^\\$?(\\d+\\.?\\d*)K$', val, re.IGNORECASE)`.
5. **if** match: branches conditionally.
6. Assigns `val_clean = re.sub('[\\$,\\s]', '', val)`.
7. **try** block with 1 **except** clause.
8. **return** value.

Code (copy-paste safe)

```
def normalize_account_size(value):
    """
    Normalize account size values to standard format: $X,XXX (v1.0.1)

    Handles:
        - "50k", "50K" → "$50,000"
```

```

- "100000", "100,000" → "$100,000"
- "$50,000" → "$50,000" (already correct)
- "5000" → "$5,000"
"""
if not value:
    return value

val = str(value).strip().upper()

# Already in correct format
if re.match(r'^\${\d,}+$', val):
    return value

# Handle "50k" or "50K" format
match = re.match(r'^\${\d+\.?\d*}K$', val, re.IGNORECASE)
if match:
    num = float(match.group(1)) * 1000
    return f"${num:,.0f}"

# Handle plain numbers like "50000" or "50,000"
val_clean = re.sub(r'[\$,\\s]', '', val)
try:
    num = float(val_clean)
    return f"${num:,.0f}"
except:
    pass

# Return original if can't parse
return value

```

```
def clean_data_structure(data)
```

Recursively cleans a data structure (dict or list) to replace NaN/Inf with None. Also converts datetime objects to ISO format strings for JSON compatibility.

Why these Python concepts were used

- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **dict comprehension** — Builds a dict in one expression (`{k: v for k, v in items}`) — same intent as a list comprehension but for mappings.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.

Step by step (top-level body)

1. **if** `isinstance(data, dict)`: branches conditionally (with an **else/elif** arm).
2. **return** data.

Code (copy-paste safe)

```

def clean_data_structure(data):
    """
    Recursively cleans a data structure (dict or list) to replace NaN/Inf with None.
    Also converts datetime objects to ISO format strings for JSON compatibility.
    """
    if isinstance(data, dict):

```

```

        return {k: clean_data_structure(v) for k, v in data.items()}
    elif isinstance(data, list):
        return [clean_data_structure(v) for v in data]
    elif isinstance(data, float):
        if math.isnan(data) or math.isinf(data):
            return None
        return data
    elif hasattr(data, 'isoformat'):
        return data.isoformat()
    return data

```

```
def calculate_derived_metrics(df)
```

Applies Excel formulas to the DataFrame to ensure consistency with the Google Sheet.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.

Step by step (top-level body)

1. Defines a nested function `get_val(...)`.
2. Defines a nested function `is_blank(...)`.
3. **for** `col` in `['Hedge Net', 'Hedge Net.1']`: iterates.
4. **for** `(index, row)` in `df.iterrows()`: iterates.
5. **return** `df`.

Code (copy-paste safe)

```

def calculate_derived_metrics(df):
    """
    Applies Excel formulas to the DataFrame to ensure consistency with the Google Sheet.
    """
    # Helper to safely get float value
    def get_val(row, col):

def fetch_evaluations(sheet_url)

```

Fetches evaluation data from a public Google Sheet CSV export. Finds the header row dynamically by looking for 'Prop Firm'. Also handles proper gid (Sheet ID) extraction from URL fragments. Fetches CSV (values) and XLSX (comments) in parallel for performance.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **dict comprehension** — Builds a dict in one expression (`{k: v for k, v in items}`) — same intent as a list comprehension but for mappings.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **raise** — Raises an exception explicitly. Either signals an invalid argument the caller should fix, or re-raises after logging.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.
- **global** — Rebinds a module-level name from inside the function. A smell in larger codebases — usually means a singleton or cache that could be passed in instead.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Imports `urllib.parse` (lazy import inside the function).
2. Imports `concurrent.futures` (lazy import inside the function).
3. Assigns `sheet_url = sheet_url.strip()`.
4. **if** `'docs.google.com/spreadsheets'` not in `sheet_url`: branches conditionally.
5. Assigns `parsed = urllib.parse.urlparse(sheet_url)`.
6. **try** block with 1 **except** clause.
7. Assigns `gid = None`.
8. Assigns `query_params = urllib.parse.parse_qs(parsed.query)`.
9. **if** `'gid'` in `query_params`: branches conditionally.
10. **if** not `gid` and `parsed.fragment`: branches conditionally.
11. Defines a nested function `_fetch_xlsx_comments(...)`.
12. Defines a nested function `_fetch_csv_data(...)`.
13. **with** `concurrent.futures.ThreadPoolExecutor()`: enters a context manager.
14. **return** `(raw_data, xlsx_notes)`.

Code (copy-paste safe)

```
def fetch_evaluations(sheet_url):
    """
    Fetches evaluation data from a public Google Sheet CSV export.
    Finds the header row dynamically by looking for 'Prop Firm'.
    Also handles proper gid (Sheet ID) extraction from URL fragments.
    Fetches CSV (values) and XLSX (comments) in parallel for performance.

```

```
def parse_currency(val)
```

Parses a currency string (e.g., '\$100,000', '\$1,234.56') to a float. Returns 0.0 for values Google Sheets cannot parse as numbers, so that our SUM logic matches sheet SUM() behaviour exactly.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

Step by step (top-level body)

1. if val is None: branches conditionally.
2. try block with 1 except clause.

Code (copy-paste safe)

```
def parse_currency(val):
    """
```

```

```

```

def calculate_statistics(evaluations, mt5_deals=None, mt5_account=None, xlsx_notes=None,
    historical_accounts=None)

```

Calculates detailed statistics matching the 'Stats' sheet structure. Uses exact SUMIF logic from Google Sheet formulas. If xlsx_notes contains Stats tab values (from XLSX export), uses those for the cashflow section to guarantee exact match with Google Sheets. historical_accounts: list of previous MT5 accounts to include in discrepancy calc.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression ([f(x) for x in xs]). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.

- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

```

```
def extract_unique_values(data)
```

Extracts unique values for dropdown fields from the data. Merges with default options to ensure a good baseline.

Why these Python concepts were used

- **dict comprehension** — Builds a dict in one expression (`{k: v for k, v in items}`) — same intent as a list comprehension but for mappings.

Step by step (top-level body)

1. Assigns options = {'Prop Firm': {'My Funded Futures', 'FundedNext', 'Fundin....
2. **if** not data: branches conditionally.
3. **for** row in data: iterates.
4. **return** {k: sorted(list(v)) for k, v in options.items()}.

Code (copy-paste safe)

```

def extract_unique_values(data):
    """
    Extracts unique values for dropdown fields from the data.
    Merges with default options to ensure a good baseline.
    """
    # Default options (baseline)
    options = {
        'Prop Firm': {'My Funded Futures', 'FundedNext', 'Funding Ticks', 'Topstep', 'Lucid', 'TradeDay',
            'Alpha Futures', 'Tradeify', 'Top One Futures', 'Other'},
        'Account Size': {'$5,000', '$10,000', '$25,000', '$50,000', '$100,000', '$200,000'},
    }

```

```

        'Status': {'Active', 'Passed', 'Breached', 'Closed', 'Payout'}
    }

    if not data:
        return {k: sorted(list(v)) for k, v in options.items()}

    for row in data:
        # Prop Firm
        val = row.get('Prop Firm')
        if val: options['Prop Firm'].add(normalize_prop_firm(str(val).strip()))

        # Account Size - normalize to standard format
        val = row.get('Account Size')
        if val:
            normalized = normalize_account_size(val)
            options['Account Size'].add(normalized)

        # Status (P1)
        val = row.get('Status P1')
        if val: options['Status'].add(str(val).strip())

        # Status (Funded)
        val = row.get('Status')
        if val: options['Status'].add(str(val).strip())

    # Return sorted lists
    return {k: sorted(list(v)) for k, v in options.items()}

```

```
def group_deals_by_position(deals)
```

Groups a list of MT5 deals by position_id to form complete trades.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns positions = defaultdict(list).
2. for deal in deals: iterates.

3. Assigns trades = [].
4. for (pos_id, pos_deals) in positions.items(): iterates.
5. return trades.

Code (copy-paste safe)

```
def group_deals_by_position(deals):
    """
    Groups a list of MT5 deals by position_id to form complete trades.
    """
    positions = defaultdict(list)

    for deal in deals:
        # Access attributes safely (handle both object and dict)
        try:
            if isinstance(deal, dict):
                pos_id = deal.get('position_id')
            else:
                pos_id = getattr(deal, 'position_id', None)
        except:
            continue

        if pos_id is not None:
            positions[pos_id].append(deal)

    trades = []
    for pos_id, pos_deals in positions.items():
        if not pos_deals:
            continue

        # Sort by time to find entry and exit
        # Handle both object and dict access for 'time'
        pos_deals.sort(key=lambda x: x.get('time') if isinstance(x, dict) else getattr(x, 'time', 0))

        first_deal = pos_deals[0]
        last_deal = pos_deals[-1]

        # Helper to get value
        def get_val(obj, attr, default=0.0):
            if isinstance(obj, dict):
                return obj.get(attr, default)
            return getattr(obj, attr, default)

        # Aggregate values
        total_profit = sum(get_val(d, 'profit') for d in pos_deals)
        total_swap = sum(get_val(d, 'swap') for d in pos_deals)
        total_commission = sum(get_val(d, 'commission') for d in pos_deals)
        net_profit = total_profit + total_swap + total_commission

        # Basic info from first deal (Entry)
        symbol = get_val(first_deal, 'symbol', '')
        deal_type = get_val(first_deal, 'type', 0)
        volume = get_val(first_deal, 'volume', 0.0)
        open_time = get_val(first_deal, 'time', 0)
        open_price = get_val(first_deal, 'price', 0.0)

        # Exit info
        close_time = get_val(last_deal, 'time', 0)
        close_price = get_val(last_deal, 'price', 0.0)
```

```

trades.append({
    "position_id": pos_id,
    "symbol": symbol,
    "type": "BUY" if deal_type == 0 else "SELL",
    "volume": clean_float(volume),
    "open_time": datetime.fromtimestamp(open_time).strftime('%Y-%m-%d %H:%M'),
    "open_price": clean_float(open_price),
    "close_time": datetime.fromtimestamp(close_time).strftime('%Y-%m-%d %H:%M'),
    "close_price": clean_float(close_price),
    "net_profit": clean_float(round(net_profit, 2))
})

return trades

```

```
def serialize_positions(positions)
```

Converts MT5 position objects to dictionaries.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns data = [].
2. if positions is None: branches conditionally.
3. for pos in positions: iterates.
4. return data.

Code (copy-paste safe)

```

def serialize_positions(positions):
    """
    Converts MT5 position objects to dictionaries.
    """
    data = []
    if positions is None:
        return data

    for pos in positions:
        try:
            data.append({
                "ticket": getattr(pos, 'ticket', 0),
                "symbol": getattr(pos, 'symbol', ''),
                "type": "BUY" if getattr(pos, 'type', 0) == 0 else "SELL",
                "volume": clean_float(getattr(pos, 'volume', 0.0)),
                "open_price": clean_float(getattr(pos, 'price_open', 0.0)),
                "current_price": clean_float(getattr(pos, 'price_current', 0.0)),
                "sl": clean_float(getattr(pos, 'sl', 0.0)),
                "tp": clean_float(getattr(pos, 'tp', 0.0)),
                "swap": clean_float(getattr(pos, 'swap', 0.0)),
                "profit": clean_float(getattr(pos, 'profit', 0.0))
            })
        except:
            pass
    return data

```

```

    })
except:
    continue
return data

```

```
def serialize_account_info(account)
```

Converts MT5 account info object to dictionary.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

Step by step (top-level body)

1. **if** account is None: branches conditionally.
2. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

def serialize_account_info(account):
    """
    Converts MT5 account info object to dictionary.
    """
    if account is None:
        return {}

    try:
        return {
            "login": getattr(account, 'login', 0),
            "balance": clean_float(getattr(account, 'balance', 0.0)),
            "equity": clean_float(getattr(account, 'equity', 0.0)),
            "profit": clean_float(getattr(account, 'profit', 0.0)),
            "margin": clean_float(getattr(account, 'margin', 0.0)),
            "margin_free": clean_float(getattr(account, 'margin_free', 0.0)),
            "margin_level": clean_float(getattr(account, 'margin_level', 0.0))
        }
    except:
        return {}

```

Checkpoint — what works now. You have a configured project skeleton. Nothing runs yet — the foundations layer is pure data and helpers — but every later phase imports from these modules. Import them in a Python REPL (`python -c "from config.settings import *; print('OK')"`) to confirm there are no syntax errors before moving on.

Chapter 4 — Phase 2 — Persistence: the database layer

Trading data has to live somewhere — accounts, payouts, watermarks, deals, notes. We use PostgreSQL in production and SQLite for development, talking to both through SQLAlchemy. Alembic owns the schema: each version file describes a forward step ("add this column") and a rollback step ("drop it"). In this phase we wire the engine, declare the ORM models that mirror the tables, and scaffold the first two Alembic revisions.

Files we build in this phase, in order:

- alembic/env.py
- alembic/versions/44e368d8bfce_initial_schema.py
- alembic/versions/5b29b54b57fa_add_firm_billing_column.py
- dashboard/database.py
- dashboard/db.py
- dashboard/models.py

Python concepts you'll meet in this phase

- Type hints (4) · Context managers (with-statements) (2) · Generators and yield (2) · Classes and objects (2) · f-strings (2) · Exceptions (2) · Dunder methods (1) · Properties (1)

Each is explained in Chapter 2 (the primer). The number in parentheses is how many of this phase's files use that concept.

Step 4.1 — Build alembic/env.py

What to do. Create the file alembic/env.py in your project root and paste in the code shown in this step. The file is **85** lines long; we walk through it piece by piece below.

Depends on. This file imports from internal modules built in earlier steps: alembic, dashboard. If any of those imports fail, jump back to the step that introduced them.

What this file is for. Alembic environment hook. Configures the migration runner.

alembic/env.py

85 loc · 0 classes · 2 functions · 7 imports

Alembic environment hook. Configures the migration runner. It defines **2** module-level functions, across **85** lines.

Python concepts demonstrated in this module

- Context managers (with-statements)
- Type hints

Imports — what each one is for

```
import os
```

Why imported. Operating-system interface. Path manipulation, environment variables, working-directory operations, exit codes, and thin wrappers around POSIX/Windows syscalls.

Used in this file. `os.environ`

Example. `os.path.join(root, 'subdir', 'file.txt')` # joins with the OS-correct separator

Other common scenarios.

- `os.environ.get('API_KEY')` to read environment variables
- `os.makedirs(path, exist_ok=True)` to create nested directories
- `os.listdir(path)` to list a directory's contents
- `os.remove(path)` / `os.rename(src, dst)` to delete or move a file
- `os.getcwd()` / `os.chdir(path)` to inspect or change the working dir

```
from logging.config import fileConfig
```

Why imported. Structured, levelled logging. Replaces `print()` with filterable, formattable output that can route to files, stderr, syslog, or HTTP endpoints.

Used in this file. `fileConfig`

Example. `logging.getLogger(__name__).info('connected to %s', host)`

Other common scenarios.

- `.debug()` / `.info()` / `.warning()` / `.error()` / `.exception()`
- `logger.exception()` captures the current traceback automatically
- `logging.basicConfig(level=logging.INFO)` for quick setup
- Handlers and Formatters route logs to files / streams / syslog

```
from dotenv import load_dotenv
```

Why imported. `python-dotenv` — load `.env` files into `os.environ` for twelve-factor configuration in development.

Used in this file. `load_dotenv`

Example. `load_dotenv()` # call once at process start

Other common scenarios.

- `dotenv_values('.env')` returns a dict without polluting `os.environ`
- Use a real secret store in production (vault, AWS SM, etc.)

```
from sqlalchemy import engine_from_config
```

```
from sqlalchemy import pool
```

Why imported. Python's most popular ORM and SQL toolkit. Models declare tables as classes; the engine handles connection pooling.

Used in this file. `engine_from_config`, `pool`

Example. `session.query(User).filter_by(email=e).first()`

Other common scenarios.

- Column / relationship / ForeignKey declare schema
- `session.add(obj)`; `session.commit()`
- with `engine.begin()` as `conn`: `conn.execute(text('SQL'))`
- 2.0-style: `select(User).where(User.id == 1)`

```
from alembic import context
```

Why imported. Migration framework that pairs with SQLAlchemy. Each version file describes a forward + rollback step.

Used in this file. `context`

Example. `alembic upgrade head` # apply all pending migrations

Other common scenarios.

- `alembic revision --autogenerate -m 'msg'` diffs models vs DB
- `op.add_column` / `op.drop_column` / `op.alter_column` inside a version

```
from dashboard.models import Base
```

Why imported. Internal package — the Flask dashboard. See chapter on dashboard/.

Used in this file. `Base`

Functions

```
def run_migrations_offline() -> None
```

Run migrations in 'offline' mode. This configures the context with just a URL and not an Engine, though an Engine is acceptable here as well. By skipping the Engine creation we don't even need a DBAPI to be available. Calls to `context.execute()` here emit the given string to the script output.

Why these Python concepts were used

- **return type annotation** — Annotated return type `-> None`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. Assigns `url = config.get_main_option('sqlalchemy.url')`.
2. Calls `context.configure(...)` for its side effect.
3. **with** `context.begin_transaction()`: enters a context manager.

Code (copy-paste safe)

```
def run_migrations_offline() -> None:
    """Run migrations in 'offline' mode.

    This configures the context with just a URL
    and not an Engine, though an Engine is acceptable
    here as well. By skipping the Engine creation
    we don't even need a DBAPI to be available.

    Calls to context.execute() here emit the given string to the
    script output.

    """
    url = config.get_main_option("sqlalchemy.url")
    context.configure(
        url=url,
        target_metadata=target_metadata,
        literal_binds=True,
        dialect_opts={"paramstyle": "named"},
    )

    with context.begin_transaction():
        context.run_migrations()

def run_migrations_online() -> None
```

Run migrations in 'online' mode. In this scenario we need to create an Engine and associate a connection with the context.

Why these Python concepts were used

- **return type annotation** — Annotated return type -> None. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. Assigns `connectable = engine_from_config(config.get_section(config.config_ini_s....`
2. **with** `connectable.connect()`: enters a context manager.

Code (copy-paste safe)

```
def run_migrations_online() -> None:
    """Run migrations in 'online' mode.

    In this scenario we need to create an Engine
    and associate a connection with the context.

    """
    connectable = engine_from_config(
        config.get_section(config.config_ini_section, {}),
        prefix="sqlalchemy.",
        poolclass=pool.NullPool,
    )

    with connectable.connect() as connection:
```

```

context.configure(
    connection=connection, target_metadata=target_metadata
)

with context.begin_transaction():
    context.run_migrations()

```

Step 4.2 — Build alembic/versions/44e368d8bfce_initial_schema.py

What to do. Create the file `alembic/versions/44e368d8bfce_initial_schema.py` in your project root and paste in the code shown in this step. The file is **266** lines long; we walk through it piece by piece below.

Depends on. This file imports from internal modules built in earlier steps: `alembic`. If any of those imports fail, jump back to the step that introduced them.

alembic/versions/44e368d8bfce_initial_schema.py

266 loc · 0 classes · 2 functions · 3 imports

It defines **2** module-level functions, across **266** lines. Module docstring: *initial_schema*

Module docstring

`initial_schema`

Python concepts demonstrated in this module

- Type hints

Imports — what each one is for

```

from typing import Sequence
from typing import Union

```

Why imported. Type-hint primitives — generics, unions, `Optional`, `Callable`, `Protocol`, `TypeVar`, `TypedDict`.

Used in this file. `Sequence`, `Union`

Example. `def lookup(k: str) -> Optional[int]: ...`

Other common scenarios.

- `List[int]` / `Dict[str, Any]` / `Tuple[int, str]` (or bare `list[int]`+ on 3.9+)
- `Callable[[int, int], int]` for function signatures
- `Protocol` for structural typing (duck typing with checks)

- `TypeVar('T')` for generic functions and classes

```
from alembic import op
```

Why imported. Migration framework that pairs with SQLAlchemy. Each version file describes a forward + rollback step.

Used in this file. `op`

Example. `alembic upgrade head # apply all pending migrations`

Other common scenarios.

- `alembic revision --autogenerate -m 'msg'` diffs models vs DB
- `op.add_column` / `op.drop_column` / `op.alter_column` inside a version

```
import sqlalchemy as sa
```

Why imported. Python's most popular ORM and SQL toolkit. Models declare tables as classes; the engine handles connection pooling.

Used in this file. `sa.Column`, `sa.Float`, `sa.ForeignKeyConstraint`, `sa.Integer`, `sa.PrimaryKeyConstraint`, `sa.SmallInteger`, `sa.Text`, `sa.UniqueConstraint`

Example. `session.query(User).filter_by(email=e).first()`

Other common scenarios.

- `Column` / `relationship` / `ForeignKey` declare schema
- `session.add(obj); session.commit()`
- `with engine.begin() as conn: conn.execute(text('SQL'))`
- 2.0-style: `select(User).where(User.id == 1)`

Functions

```
def upgrade() -> None
```

Upgrade schema.

Why these Python concepts were used

- **return type annotation** — Annotated return type `-> None`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. Calls `op.create_table(...)` for its side effect.
2. Calls `op.create_table(...)` for its side effect.
3. Calls `op.create_table(...)` for its side effect.
4. Calls `op.create_table(...)` for its side effect.
5. Calls `op.create_table(...)` for its side effect.
6. Calls `op.create_table(...)` for its side effect.
7. Calls `op.create_index(...)` for its side effect.

8. Calls `op.create_index(...)` for its side effect.
9. Calls `op.create_table(...)` for its side effect.
10. Calls `op.create_table(...)` for its side effect.
11. Calls `op.create_index(...)` for its side effect.
12. Calls `op.create_table(...)` for its side effect.
13. Calls `op.create_table(...)` for its side effect.
14. Calls `op.create_index(...)` for its side effect.
15. ... and 9 more statement(s) in the body.

Code (copy-paste safe)

```
def upgrade() -> None:
    """Upgrade schema."""
    # ### commands auto generated by Alembic - please adjust! ###
    op.create_table('admin_passwords',
        sa.Column('id', sa.Integer(), autoincrement=True, nullable=False),
        sa.Column('username', sa.Text(), nullable=False),
        sa.Column('password_hash', sa.Text(), nullable=False),
        sa.Column('salt', sa.Text(), nullable=False),

sa.Column('period_high', sa.Float(), nullable=True),
sa.Column('split_pct', sa.Integer(), server_default=sa.text('50'), nullable=True),
sa.PrimaryKeyConstraint('client_id', 'from_date')
)

```

```
def downgrade() -> None
```

Downgrade schema.

Why these Python concepts were used

- **return type annotation** — Annotated return type -> None. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. Calls `op.drop_table(...)` for its side effect.
2. Calls `op.drop_table(...)` for its side effect.
3. Calls `op.drop_table(...)` for its side effect.
4. Calls `op.drop_table(...)` for its side effect.
5. Calls `op.drop_index(...)` for its side effect.
6. Calls `op.drop_table(...)` for its side effect.
7. Calls `op.drop_table(...)` for its side effect.
8. Calls `op.drop_table(...)` for its side effect.
9. Calls `op.drop_index(...)` for its side effect.
10. Calls `op.drop_index(...)` for its side effect.
11. Calls `op.drop_table(...)` for its side effect.
12. Calls `op.drop_table(...)` for its side effect.
13. Calls `op.drop_index(...)` for its side effect.
14. Calls `op.drop_table(...)` for its side effect.
15. ... and 9 more statement(s) in the body.

Code (copy-paste safe)

```
def downgrade() -> None:
    """Downgrade schema."""
    # ### commands auto generated by Alembic - please adjust! ###
    op.drop_table('waterlog_periods')
    op.drop_table('user_credentials')
    op.drop_table('system_settings')
    op.drop_table('sessions')
    op.drop_index('idx_quality_scan_date', table_name='quality_scan_results')
    op.drop_table('quality_scan_results')
    op.drop_table('phase_definitions')
    op.drop_table('login_attempts')
    op.drop_index('idx_kyc_primary', table_name='kyc_links')
    op.drop_index('idx_kyc_linked', table_name='kyc_links')
    op.drop_table('kyc_links')
    op.drop_table('evaluations')
    op.drop_index('idx_data_history_client', table_name='data_history')
    op.drop_table('data_history')
    op.drop_table('daily_watermarks')
    op.drop_index('idx_checklist_date', table_name='daily_checklists')
    op.drop_index('idx_checklist_client', table_name='daily_checklists')
    op.drop_table('daily_checklists')
    op.drop_table('clients_data')
    op.drop_table('cell_notes')
    op.drop_table('audit_log')
    op.drop_table('api_keys')
    op.drop_table('admin_passwords')
```

Step 4.3 — Build alembic/versions/5b29b54b57fa_add_firm_billing_column.py

What to do. Create the file `alembic/versions/5b29b54b57fa_add_firm_billing_column.py` in your project root and paste in the code shown in this step. The file is **31** lines long; we walk through it piece by piece below.

Depends on. This file imports from internal modules built in earlier steps: `alembic`. If any of those imports fail, jump back to the step that introduced them.

`alembic/versions/5b29b54b57fa_add_firm_billing_column.py`

31 loc · 0 classes · 2 functions · 3 imports

It defines **2** module-level functions, across **31** lines. Module docstring: `add_firm_billing_column`

Module docstring

`add_firm_billing_column`

Revision ID: 5b29b54b57fa Revises: 44e368d8bfce Create Date: 2026-04-14 17:23:49.376388

Python concepts demonstrated in this module

- Type hints

Imports — what each one is for

```
from typing import Sequence
from typing import Union
```

Why imported. Type-hint primitives — generics, unions, `Optional`, `Callable`, `Protocol`, `TypeVar`, `TypedDict`.

Used in this file. `Sequence`, `Union`

Example. `def lookup(k: str) -> Optional[int]: ...`

Other common scenarios.

- `List[int]` / `Dict[str, Any]` / `Tuple[int, str]` (or bare `list[int]`+ on 3.9+)
- `Callable[[int, int], int]` for function signatures
- `Protocol` for structural typing (duck typing with checks)
- `TypeVar('T')` for generic functions and classes

```
from alembic import op
```

Why imported. Migration framework that pairs with `SQLAlchemy`. Each version file describes a forward + rollback step.

Used in this file. `op`

Example. `alembic upgrade head # apply all pending migrations`

Other common scenarios.

- `alembic revision --autogenerate -m 'msg'` diffs models vs DB
- `op.add_column / op.drop_column / op.alter_column` inside a version

```
import sqlalchemy as sa
```

Why imported. Python's most popular ORM and SQL toolkit. Models declare tables as classes; the engine handles connection pooling.

Used in this file. `sa.Column`, `sa.Text`

Example. `session.query(User).filter_by(email=e).first()`

Other common scenarios.

- `Column / relationship / ForeignKey` declare schema
- `session.add(obj); session.commit()`
- with `engine.begin()` as `conn: conn.execute(text('SQL'))`
- 2.0-style: `select(User).where(User.id == 1)`

Functions

```
def upgrade() -> None
```

Upgrade schema.

Why these Python concepts were used

- **return type annotation** — Annotated return type `-> None`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. Calls `op.add_column(...)` for its side effect.

Code (copy-paste safe)

```
def upgrade() -> None:
    """Upgrade schema."""
    op.add_column('clients_data', sa.Column('firm_billing', sa.Text(), server_default='{}'))
```

```
def downgrade() -> None
```

Downgrade schema.

Why these Python concepts were used

- **return type annotation** — Annotated return type `-> None`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. Calls `op.drop_column(...)` for its side effect.

2. `pass` (placeholder).

Code (copy-paste safe)

```
def downgrade() -> None:
    """Downgrade schema."""
    op.drop_column('clients_data', 'firm_billing')
    pass
```

Step 4.4 — Build dashboard/database.py

What to do. Create the file `dashboard/database.py` in your project root and paste in the code shown in this step. The file is **1940** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

What this file is for. Database engine and session factory. The single source of connections used across the app.

dashboard/database.py

1940 loc · 2 classes · 90 functions · 11 imports

Database engine and session factory. The single source of connections used across the app. It defines **2** classes and **90** module-level functions, across **1,940** lines. Module docstring: *PostgreSQL Database Module for Trading Dashboard*

Module docstring

PostgreSQL Database Module for Trading Dashboard Provides secure storage with encrypted data and audit logging.

Migrated from SQLite — uses `psycopg2` with compatibility wrappers so all existing query code (? placeholders, `row['col']` access) keeps working.

Python concepts demonstrated in this module

- Classes and objects
- Comprehensions
- Context managers (with-statements)
- Decorators
- Dunder methods
- Exceptions
- f-strings
- Generators and yield
- Module-level state
- Properties
- Type hints

Imports — what each one is for

```
import json
```

Why imported. JSON encoding and decoding — the standard wire format for config files, API payloads, and inter-process messages.

Used in this file. `json.dumps`, `json.load`, `json.loads`

Example. `json.loads(response.text)` # parse a JSON string to dict

Other common scenarios.

- `json.dumps(obj, indent=2)` for pretty-printing
- `json.dump(obj, file)` / `json.load(file)` for file I/O
- `default=str` handles non-serialisable types like `datetime`
- `object_hook=` customises decoding (e.g., to `dataclass` instances)

`import os`

Why imported. Operating-system interface. Path manipulation, environment variables, working-directory operations, exit codes, and thin wrappers around POSIX/Windows syscalls.

Used in this file. `os.environ`, `os.environ.get`, `os.path`, `os.path.abspath`, `os.path.dirname`, `os.path.exists`, `os.path.join`

Example. `os.path.join(root, 'subdir', 'file.txt')` # joins with the OS-correct separator

Other common scenarios.

- `os.environ.get('API_KEY')` to read environment variables
- `os.makedirs(path, exist_ok=True)` to create nested directories
- `os.listdir(path)` to list a directory's contents
- `os.remove(path)` / `os.rename(src, dst)` to delete or move a file
- `os.getcwd()` / `os.chdir(path)` to inspect or change the working dir

`import hashlib`

Why imported. Cryptographic hash functions — SHA-256, MD5, BLAKE2.

Used in this file. `hashlib.pbkdf2_hmac`, `hashlib.sha256`

Example. `hashlib.sha256(b'hello').hexdigest()`

Other common scenarios.

- Pass data in chunks via `.update()` to hash large files
- Use `sha256` / `sha512` for integrity; never MD5 or SHA-1 for security
- For password hashing use `bcrypt/argon2`, NOT raw `hashlib`

`import secrets`

Why imported. Cryptographically strong randomness — tokens, session IDs, API keys. Never use `random` for anything security-sensitive.

Used in this file. `secrets.compare_digest`, `secrets.token_hex`, `secrets.token_urlsafe`

Example. `secrets.token_urlsafe(32)` # 32-byte url-safe random string

Other common scenarios.

- `secrets.token_hex(n)` for a hex string
- `secrets.choice(seq)` is the cryptographic equivalent of `random.choice`
- `secrets.compare_digest(a, b)` for timing-safe comparison

```
import psycopg2
```

Why imported. PostgreSQL driver. Used directly for raw SQL paths and as the dialect SQLAlchemy talks through.

Used in this file. *No direct attribute access detected — likely imported for side effects, re-export, or string references.*

Example. `psycopg2.connect(dsn)`

Other common scenarios.

- Always use parameterised queries: `cur.execute('... WHERE id=%s', (id,))`
- `psycopg2.extras.RealDictCursor` returns dict-like rows
- On 3+ the modern replacement is `psycopg` (`psycopg3`)

```
import psycopg2.extras
```

Why imported. PostgreSQL driver. Used directly for raw SQL paths and as the dialect SQLAlchemy talks through.

Used in this file. *No direct attribute access detected — likely imported for side effects, re-export, or string references.*

Example. `psycopg2.connect(dsn)`

Other common scenarios.

- Always use parameterised queries: `cur.execute('... WHERE id=%s', (id,))`
- `psycopg2.extras.RealDictCursor` returns dict-like rows
- On 3+ the modern replacement is `psycopg` (`psycopg3`)

```
import psycopg2.pool
```

Why imported. PostgreSQL driver. Used directly for raw SQL paths and as the dialect SQLAlchemy talks through.

Used in this file. `psycopg2.IntegrityError`, `psycopg2.OperationalError`, `psycopg2.extras`, `psycopg2.extras.RealDictCursor`, `psycopg2.pool`, `psycopg2.pool.SimpleConnectionPool`

Example. `psycopg2.connect(dsn)`

Other common scenarios.

- Always use parameterised queries: `cur.execute('... WHERE id=%s', (id,))`
- `psycopg2.extras.RealDictCursor` returns dict-like rows
- On 3+ the modern replacement is `psycopg` (`psycopg3`)

```
import logging
```

Why imported. Structured, levelled logging. Replaces `print()` with filterable, formattable output that can route to files, stderr, syslog, or HTTP endpoints.

Used in this file. `logging.getLogger`, `logging.info`

Example. `logging.getLogger(__name__).info('connected to %s', host)`

Other common scenarios.

- `.debug()` / `.info()` / `.warning()` / `.error()` / `.exception()`
- `logger.exception()` captures the current traceback automatically
- `logging.basicConfig(level=logging.INFO)` for quick setup
- Handlers and Formatters route logs to files / streams / syslog

```
from datetime import datetime
from datetime import timedelta
```

Why imported. Dates, times, durations. The fundamental temporal types: `date`, `time`, `datetime`, `timedelta`, `timezone`.

Used in this file. `datetime`, `timedelta`

Example. `datetime.now() - timedelta(days=7)` # one week ago

Other common scenarios.

- `datetime.strptime(s, '%Y-%m-%d')` parses a string
- `datetime.strftime(fmt)` formats one
- `datetime.fromtimestamp(n)` converts a Unix epoch
- `datetime.utcnow()` for UTC (better: `datetime.now(timezone.utc)`)

```
from contextlib import contextmanager
```

Why imported. Context-manager helpers. `@contextmanager` turns a generator into a with-block; `suppress()` swallows specific exceptions.

Used in this file. `contextmanager`

Example. `@contextmanager\ndef timer():\n t=time.time(); yield; print(time.time()-t)`

Other common scenarios.

- `ExitStack` stacks dynamic context managers (close many at once)
- `suppress(FileNotFoundError)` ignores a specific exception
- `closing(obj)` wraps any `close()`-able as a context manager

```
from dotenv import load_dotenv
```

Why imported. `python-dotenv` — load `.env` files into `os.environ` for twelve-factor configuration in development.

Used in this file. `load_dotenv`

Example. `load_dotenv()` # call once at process start

Other common scenarios.

- `dotenv_values('.env')` returns a dict without polluting `os.environ`
- Use a real secret store in production (vault, AWS SM, etc.)

Module constants

Each line below is followed by a plain-English note explaining what it does and why it is written that way.

```
DATABASE_URL = os.environ.get('DATABASE_URL', 'postgresql://postgres:postgres123@localhost:5432/tradeopss')
```

Equivalent to `os.getenv`: reads `DATABASE_URL` from the environment, default `'postgresql://postgres:postgres123@localhost:5432/tradeopss'`.

Classes

```
class _PgCursorWrapper
```

Wraps psycopg2 RealDictCursor; translates ? → %s.

Code (copy-paste safe)

```
class _PgCursorWrapper:
    """Wraps psycopg2 RealDictCursor; translates ? → %s."""

    def __init__(self, cursor):
        self._cursor = cursor

    def execute(self, sql, params=None):
        sql = sql.replace('?', '%s')
        self._cursor.execute(sql, params)
        return self

    def executemany(self, sql, params_list):
        sql = sql.replace('?', '%s')
        self._cursor.executemany(sql, params_list)
        return self

    def fetchone(self):
        return self._cursor.fetchone()

    def fetchall(self):
        return self._cursor.fetchall()

    @property
    def rowcount(self):
        return self._cursor.rowcount

    @property
    def lastrowid(self):
        return getattr(self._cursor, 'lastrowid', None)
```

Method: `_PgCursorWrapper.__init__`

```
def __init__(self, cursor)
```

Why these Python concepts were used

- `__init__` — The constructor. Runs after Python has allocated the instance; assigns starting attribute values to `self`.

Step by step (top-level body)

1. Assigns `self._cursor = cursor`.

Code (copy-paste safe)

```
def __init__(self, cursor):
```

```
self._cursor = cursor
```

Method: `_PgCursorWrapper.execute`

```
def execute(self, sql, params=None)
```

Step by step (top-level body)

1. Assigns `sql = sql.replace('?', '%s')`.
2. Calls `self._cursor.execute(...)` for its side effect.
3. **return** `self`.

Code (copy-paste safe)

```
def execute(self, sql, params=None):
    sql = sql.replace('?', '%s')
    self._cursor.execute(sql, params)
    return self
```

Method: `_PgCursorWrapper.executemany`

```
def executemany(self, sql, params_list)
```

Step by step (top-level body)

1. Assigns `sql = sql.replace('?', '%s')`.
2. Calls `self._cursor.executemany(...)` for its side effect.
3. **return** `self`.

Code (copy-paste safe)

```
def executemany(self, sql, params_list):
    sql = sql.replace('?', '%s')
    self._cursor.executemany(sql, params_list)
    return self
```

Method: `_PgCursorWrapper.fetchone`

```
def fetchone(self)
```

Step by step (top-level body)

1. **return** `self._cursor.fetchone()`.

Code (copy-paste safe)

```
def fetchone(self):
    return self._cursor.fetchone()
```

Method: `_PgCursorWrapper.fetchall`

```
def fetchall(self)
```

Step by step (top-level body)

1. **return** `self._cursor.fetchall()`.

Code (copy-paste safe)

```
def fetchall(self):
    return self._cursor.fetchall()
```

Method: `_PgCursorWrapper.rowcount`

```
@property
def rowcount(self)
```

Why these Python concepts were used

- **@property** — Wrapped in **@property** so callers access the value with attribute syntax (`obj.x`) instead of a method call. Lets the implementation compute or validate the value lazily without changing the call site.

Step by step (top-level body)

1. **return** `self._cursor.rowcount`.

Code (copy-paste safe)

```
def rowcount(self):
    return self._cursor.rowcount
```

Method: `_PgCursorWrapper.lastrowid`

```
@property
def lastrowid(self)
```

Why these Python concepts were used

- **@property** — Wrapped in **@property** so callers access the value with attribute syntax (`obj.x`) instead of a method call. Lets the implementation compute or validate the value lazily without changing the call site.

Step by step (top-level body)

1. **return** `getattr(self._cursor, 'lastrowid', None)`.

Code (copy-paste safe)

```
def lastrowid(self):
    return getattr(self._cursor, 'lastrowid', None)
```

```
class _PgConnWrapper
```

Wraps a psycopg2 connection to match the sqlite3 interface used throughout.

Code (copy-paste safe)

```
class _PgConnWrapper:
    """Wraps a psycopg2 connection to match the sqlite3 interface used throughout."""

    def __init__(self, raw_conn):
        self._conn = raw_conn

    def cursor(self):
```

```

        return _PgCursorWrapper(
            self._conn.cursor(cursor_factory=psycopg2.extras.RealDictCursor)
        )

    def execute(self, sql, params=None):
        cur = self.cursor()
        cur.execute(sql, params)
        return cur

    def commit(self):
        self._conn.commit()

    def rollback(self):
        self._conn.rollback()

    def close(self):
        self._conn.close()

```

Method: `_PgConnWrapper.__init__`

```
def __init__(self, raw_conn)
```

Why these Python concepts were used

- `__init__` — The constructor. Runs after Python has allocated the instance; assigns starting attribute values to self.

Step by step (top-level body)

1. Assigns `self._conn = raw_conn`.

Code (copy-paste safe)

```
def __init__(self, raw_conn):
    self._conn = raw_conn
```

Method: `_PgConnWrapper.cursor`

```
def cursor(self)
```

Step by step (top-level body)

1. `return _PgCursorWrapper(self._conn.cursor(cursor_factory=psycopg2.extras.R....`

Code (copy-paste safe)

```
def cursor(self):
    return _PgCursorWrapper(
        self._conn.cursor(cursor_factory=psycopg2.extras.RealDictCursor)
    )
```

Method: `_PgConnWrapper.execute`

```
def execute(self, sql, params=None)
```

Step by step (top-level body)

1. Assigns `cur = self.cursor()`.
2. Calls `cur.execute(...)` for its side effect.

3. return cur.

Code (copy-paste safe)

```
def execute(self, sql, params=None):
    cur = self.cursor()
    cur.execute(sql, params)
    return cur
```

Method: _PgConnWrapper.commit

```
def commit(self)
```

Step by step (top-level body)

1. Calls self._conn.commit(...) for its side effect.

Code (copy-paste safe)

```
def commit(self):
    self._conn.commit()
```

Method: _PgConnWrapper.rollback

```
def rollback(self)
```

Step by step (top-level body)

1. Calls self._conn.rollback(...) for its side effect.

Code (copy-paste safe)

```
def rollback(self):
    self._conn.rollback()
```

Method: _PgConnWrapper.close

```
def close(self)
```

Step by step (top-level body)

1. Calls self._conn.close(...) for its side effect.

Code (copy-paste safe)

```
def close(self):
    self._conn.close()
```

Functions

```
def _init_pool()
```

Initialize the connection pool on first use.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't

have to handle it.

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

- **raise** — Raises an exception explicitly. Either signals an invalid argument the caller should fix, or re-raises after logging.

- **global** — Rebinds a module-level name from inside the function. A smell in larger codebases — usually means a singleton or cache that could be passed in instead.

Step by step (top-level body)

1. Declares globals: `_connection_pool`.
2. **if** `_connection_pool` is `None`: branches conditionally.

Code (copy-paste safe)

```
def _init_pool():
    """Initialize the connection pool on first use."""
    global _connection_pool
    if _connection_pool is None:
        try:
            _connection_pool = psycopg2.pool.SimpleConnectionPool(
                5, 15, # min=5, max=15 connections
                DATABASE_URL,
                connect_timeout=5 # 5-second timeout per connection
            )
            logger.info("[DB] Connection pool initialized (5-15 connections)")
        except Exception as e:
            logger.error(f"[DB] Failed to initialize connection pool: {e}")
            raise
```

```
def _get_pooled_connection()
```

Get a connection from the pool (creates pool on first call).

Step by step (top-level body)

1. **if** `_connection_pool` is `None`: branches conditionally.
2. **return** `_connection_pool.getconn()`.

Code (copy-paste safe)

```
def _get_pooled_connection():
    """Get a connection from the pool (creates pool on first call)."""
    if _connection_pool is None:
        _init_pool()
    return _connection_pool.getconn()
```

```
def _return_pooled_connection(conn)
```

Return a connection to the pool.

Step by step (top-level body)

1. **if** `_connection_pool` is not `None`: branches conditionally (with an **else/elif** arm).

Code (copy-paste safe)

```
def _return_pooled_connection(conn):
    """Return a connection to the pool."""
    if _connection_pool is not None:
        _connection_pool.putconn(conn)
    else:
        conn.close()
```

```
@contextmanager
def get_connection()
```

Context manager for database connections (PostgreSQL with pooling).

Why these Python concepts were used

- **@contextmanager** — Turns a generator (which **yields** exactly once) into a context manager — the code before the yield runs on enter, the code after runs on exit. A concise alternative to writing `__enter__` / `__exit__` by hand.
- **generator (yield)** — The body uses **yield**, so calling it returns an iterator instead of a value. Items are produced lazily — the function only runs as far as the next **yield** on each iteration. Right choice when the caller iterates results and the dataset is large or open-ended.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **raise** — Raises an exception explicitly. Either signals an invalid argument the caller should fix, or re-raises after logging.

Step by step (top-level body)

1. Assigns `raw = None`.
2. **try** block with 2 **except** clauses, plus a **finally**.

Code (copy-paste safe)

```
def get_connection():
    """Context manager for database connections (PostgreSQL with pooling)."""
    raw = None
    try:
        # Get connection from pool (creates pool on first call)
        raw = _get_pooled_connection()

        # Reset connection state (auto-commit off, no pending transactions)
        raw.autocommit = False
        raw.rollback() # Clear any stale state

        conn = _PgConnWrapper(raw)
        try:
            yield conn
            # Auto-commit on successful exit (safety net)
            raw.commit()
        except Exception as e:
```

```

        # Log and rollback on error
        logger.warning(f"[DB] Transaction error, rolling back: {e}")
        raw.rollback()
        raise
    except psycopg2.OperationalError as e:
        # Connection pool exhausted or DB unreachable
        logger.error(f"[DB] Database connection error (pool issue?): {e}")
        raise
    except Exception as e:
        logger.error(f"[DB] Unexpected error in get_connection: {e}")
        raise
    finally:
        # Always return connection to pool
        if raw is not None:
            _return_pooled_connection(raw)

```

```
def get_db_path()
```

Legacy helper — returns DATABASE_URL for PostgreSQL.

Step by step (top-level body)

1. **return** DATABASE_URL.

Code (copy-paste safe)

```

def get_db_path():
    """Legacy helper — returns DATABASE_URL for PostgreSQL."""
    return DATABASE_URL

```

```
def check_and_repair_database()
```

Connectivity check (PostgreSQL doesn't need SQLite-style repair).

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

def check_and_repair_database():
    """Connectivity check (PostgreSQL doesn't need SQLite-style repair)."""
    try:
        with get_connection() as conn:
            conn.execute('SELECT 1')
            return True, 'PostgreSQL connection OK'
    except Exception as e:

```

```
return False, f'PostgreSQL connection failed: {e}'
```

```
def init_database()
```

Schema is managed by Alembic migrations — verify connectivity and ensure columns exist.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def init_database():
    """Schema is managed by Alembic migrations – verify connectivity and ensure columns exist."""
    try:
        with get_connection() as conn:
            conn.execute('SELECT 1')
            conn.commit()
        print("Database connection verified (schema managed by Alembic)")
        # Defensive: ensure columns exist even if Alembic migration was stamped on legacy DB
        with get_connection() as conn:
            cursor = conn.cursor()
            for _col, _default in [('prop_accounts', "[]"), ('vps_accounts', "[]"),
                                   ('hedge_accounts', "[]"), ('mt5_credentials', "{}"),
                                   ('payment_info', "[]"), ('payment_address', "{}")]:
                try:
                    cursor.execute(
                        f"ALTER TABLE clients_data ADD COLUMN IF NOT EXISTS {_col} TEXT DEFAULT {_default}"
                    )
                except Exception:
                    pass
            conn.commit()
    except Exception as e:
        print(f"Database connection failed: {e}")
```

```
def hash_password(password: str, salt: str=None) -> tuple
```

Hash a password with salt using SHA-256 + PBKDF2.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., password: str, salt: str). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type -> tuple. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. **if** salt is None: branches conditionally.
2. Assigns password_hash = hashlib.pbkdf2_hmac('sha256', password.encode('utf-8'), s....
3. **return** (password_hash, salt).

Code (copy-paste safe)

```
def hash_password(password: str, salt: str = None) -> tuple:
    """Hash a password with salt using SHA-256 + PBKDF2."""
    if salt is None:
        salt = secrets.token_hex(32)

    # Use PBKDF2 with SHA-256
    password_hash = hashlib.pbkdf2_hmac(
        'sha256',
        password.encode('utf-8'),
        salt.encode('utf-8'),
        100000 # 100,000 iterations
    ).hex()

    return password_hash, salt
```

```
def verify_password(password: str, stored_hash: str, salt: str) -> bool
```

Verify a password against stored hash.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., password: str, stored_hash: str, salt: str). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type -> bool. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. Assigns (password_hash, _) = hash_password(password, salt).
2. **return** secrets.compare_digest(password_hash, stored_hash).

Code (copy-paste safe)

```
def verify_password(password: str, stored_hash: str, salt: str) -> bool:
    """Verify a password against stored hash."""
    password_hash, _ = hash_password(password, salt)
    return secrets.compare_digest(password_hash, stored_hash)

def set_admin_password(username: str, password: str) -> bool

    Set or update admin password.
```

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `username: str, password: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> bool`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `(password_hash, salt) = hash_password(password)`.
2. Assigns `now = datetime.now().isoformat()`.
3. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```
def set_admin_password(username: str, password: str) -> bool:
    """Set or update admin password."""
    password_hash, salt = hash_password(password)
    now = datetime.now().isoformat()

    with get_connection() as conn:
        cursor = conn.cursor()
        try:
            cursor.execute('''
                INSERT INTO admin_passwords (username, password_hash, salt, created_at)
                VALUES (?, ?, ?, ?)
                ON CONFLICT(username) DO UPDATE SET
                    password_hash = excluded.password_hash,
                    salt = excluded.salt,
                    updated_at = ?
            ''', (username, password_hash, salt, now, now))
            conn.commit()
            return True
        except Exception as e:
            print(f"Error setting admin password: {e}")
            return False
```

```
def admin_password_exists(username: str) -> bool
```

Return True if a password row already exists for the given admin username.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `username: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.

- **return type annotation** — Annotated return type -> bool. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```
def admin_password_exists(username: str) -> bool:
    """Return True if a password row already exists for the given admin username."""
    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute(
            'SELECT 1 FROM admin_passwords WHERE username = ?',
            (username,)
        )
        return cursor.fetchone() is not None
```

```
def copy_admin_password_row(from_username: str, to_username: str) -> bool
```

If to_username has no row, copy password_hash/salt from from_username. Returns True if a row was copied.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `from_username: str`, `to_username: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type -> bool. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. **if** `admin_password_exists(to_username)`: branches conditionally.
2. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```
def copy_admin_password_row(from_username: str, to_username: str) -> bool:
    """
    If to_username has no row, copy password_hash/salt from from_username.
    Returns True if a row was copied.
    """
    if admin_password_exists(to_username):
        return False
    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute(
            'SELECT password_hash, salt FROM admin_passwords WHERE username = ?',
            (from_username,)
        )
```

```

row = cursor.fetchone()
if not row:
    return False
now = datetime.now().isoformat()
cursor.execute(
    '''
        INSERT INTO admin_passwords (username, password_hash, salt, created_at)
        VALUES (?, ?, ?, ?)
    ''',
    (to_username, row['password_hash'], row['salt'], now),
)
conn.commit()
return True

```

```
def verify_admin_password(username: str, password: str) -> bool
```

Verify admin password.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `username: str`, `password: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> bool`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```

def verify_admin_password(username: str, password: str) -> bool:
    """Verify admin password."""
    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute(
            'SELECT password_hash, salt FROM admin_passwords WHERE username = ?',
            (username,)
        )
        row = cursor.fetchone()

        if row is None:
            return False

        return verify_password(password, row['password_hash'], row['salt'])

```

```

def create_user(username: str, password: str, user_type: str, email: str=None, parent_admin: str=None,
parent_trader: str=None) -> bool

```

Create a new user with hashed password.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., username: str, password: str, user_type: str). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type -> bool. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns username = username.strip().
2. Assigns (password_hash, salt) = hash_password(password).
3. Assigns now = datetime.now().isoformat().
4. **with** get_connection(): enters a context manager.

Code (copy-paste safe)

```
def create_user(username: str, password: str, user_type: str,
               email: str = None, parent_admin: str = None,
               parent_trader: str = None) -> bool:
    """Create a new user with hashed password."""
    username = username.strip()
    password_hash, salt = hash_password(password)
    now = datetime.now().isoformat()

    with get_connection() as conn:
        cursor = conn.cursor()
        try:
            cursor.execute('''
                INSERT INTO user_credentials
                (username, email, password_hash, salt, user_type, parent_admin, parent_trader, created_at)
                VALUES (?, ?, ?, ?, ?, ?, ?, ?)
            ''', (username, email, password_hash, salt, user_type, parent_admin, parent_trader, now))
            conn.commit()
            return True
        except psycopg2.IntegrityError:
            # User already exists
            conn.rollback()
            return False
        except Exception as e:
            print(f"Error creating user: {e}")
            return False

def verify_user_password(username: str, user_type: str, password: str) -> dict:
    Verify user password and return user info if valid.
```

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `username: str`, `user_type: str`, `password: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> dict`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```
def verify_user_password(username: str, user_type: str, password: str) -> dict:
    """Verify user password and return user info if valid."""
    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute('''
            SELECT id, username, email, password_hash, salt, user_type,
                   parent_admin, parent_trader, is_active, must_change_password
            FROM user_credentials
            WHERE username = ? AND user_type = ? AND is_active = 1
        ''', (username, user_type))
        row = cursor.fetchone()

        if row is None:
            return None

        if not verify_password(password, row['password_hash'], row['salt']):
            return None

        # Update last login
        cursor.execute(
            'UPDATE user_credentials SET last_login = ? WHERE id = ?',
            (datetime.now().isoformat(), row['id'])
        )
        conn.commit()

        return {
            'id': row['id'],
            'username': row['username'],
            'email': row['email'],
            'user_type': row['user_type'],
            'parent_admin': row['parent_admin'],
            'parent_trader': row['parent_trader'],
            'must_change_password': bool(row['must_change_password'])
        }

def verify_client_login(email: str, password: str) -> dict
```

Verify client login by email and password.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., email: str, password: str). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type -> dict. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. **with get_connection():** enters a context manager.

Code (copy-paste safe)

```
def verify_client_login(email: str, password: str) -> dict:
    """Verify client login by email and password."""
    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute('''
            SELECT id, username, email, password_hash, salt, user_type,
                   parent_admin, parent_trader, is_active, must_change_password
            FROM user_credentials
            WHERE email = ? AND user_type = 'client' AND is_active = 1
        ''', (email,))
        row = cursor.fetchone()

        if row is None:
            return None

        if not verify_password(password, row['password_hash'], row['salt']):
            return None

        # Update last login
        cursor.execute(
            'UPDATE user_credentials SET last_login = ? WHERE id = ?',
            (datetime.now().isoformat(), row['id'])
        )
        conn.commit()

    return {
        'id': row['id'],
        'username': row['username'],
        'email': row['email'],
        'user_type': row['user_type'],
        'parent_admin': row['parent_admin'],
        'parent_trader': row['parent_trader'],
        'must_change_password': bool(row['must_change_password'])
    }
```

```
def update_user_password(username: str, user_type: str, new_password: str) -> bool
```

Update a user's password.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., username: str, user_type: str, new_password: str). Hints are not enforced at runtime — they document intent for static checkers

(mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.

- **return type annotation** — Annotated return type -> bool. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. Assigns (password_hash, salt) = hash_password(new_password).
2. Assigns now = datetime.now().isoformat().
3. **with** get_connection(): enters a context manager.

Code (copy-paste safe)

```
def update_user_password(username: str, user_type: str, new_password: str) -> bool:
    """Update a user's password."""
    password_hash, salt = hash_password(new_password)
    now = datetime.now().isoformat()

    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute('''
            UPDATE user_credentials
            SET password_hash = ?, salt = ?, must_change_password = 0, updated_at = ?
            WHERE username = ? AND user_type = ?
        ''', (password_hash, salt, now, username, user_type))
        conn.commit()
        return cursor.rowcount > 0
```

```
def get_user(username: str, user_type: str) -> dict
```

Get user info without password verification.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., username: str, user_type: str). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type -> dict. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **with** get_connection(): enters a context manager.

Code (copy-paste safe)

```
def get_user(username: str, user_type: str) -> dict:
```

```

"""Get user info without password verification."""
with get_connection() as conn:
    cursor = conn.cursor()
    cursor.execute('''
        SELECT id, username, email, user_type, parent_admin, parent_trader,
               is_active, must_change_password, last_login, created_at
        FROM user_credentials
        WHERE username = ? AND user_type = ?
    ''', (username, user_type))
    row = cursor.fetchone()
    return dict(row) if row else None

```

```
def list_users(user_type: str=None) -> list
```

List all users, optionally filtered by type.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `user_type: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> list`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with `append`, and clearer about intent: this is a transform, not a side-effecting loop.

Step by step (top-level body)

1. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```

def list_users(user_type: str = None) -> list:
    """List all users, optionally filtered by type."""
    with get_connection() as conn:
        cursor = conn.cursor()
        if user_type:
            cursor.execute('''
                SELECT id, username, email, user_type, parent_admin, parent_trader,
                       is_active, last_login, created_at
                FROM user_credentials WHERE user_type = ?
                ORDER BY created_at DESC
            ''', (user_type,))
        else:
            cursor.execute('''
                SELECT id, username, email, user_type, parent_admin, parent_trader,
                       is_active, last_login, created_at
                FROM user_credentials ORDER BY user_type, created_at DESC
            ''')
        return [dict(row) for row in cursor.fetchall()]

```

```
def deactivate_user(username: str, user_type: str) -> bool
```

Deactivate a user account.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `username: str, user_type: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> bool`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```
def deactivate_user(username: str, user_type: str) -> bool:
    """Deactivate a user account."""
    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute(''
            UPDATE user_credentials SET is_active = 0, updated_at = ?
            WHERE username = ? AND user_type = ?
            ''', (datetime.now().isoformat(), username, user_type))
        conn.commit()
        return cursor.rowcount > 0
```

```
def activate_user(username: str, user_type: str) -> bool
```

Activate a user account.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `username: str, user_type: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> bool`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```
def activate_user(username: str, user_type: str) -> bool:
    """Activate a user account."""
    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute(''
            UPDATE user_credentials SET is_active = 1, updated_at = ?
            WHERE username = ? AND user_type = ?
            ''', (datetime.now().isoformat(), username, user_type))
```

```

conn.commit()
return cursor.rowcount > 0

```

```

def reset_user_password(username: str, user_type: str, default_password: str='Test@123') -> str

```

Reset user password to the default password.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `username: str`, `user_type: str`, `default_password: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> str`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. Assigns `(password_hash, salt) = hash_password(default_password)`.
2. Assigns `now = datetime.now().isoformat()`.
3. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```

def reset_user_password(username: str, user_type: str, default_password: str = 'Test@123') -> str:
    """Reset user password to the default password."""
    password_hash, salt = hash_password(default_password)
    now = datetime.now().isoformat()

    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute('''
            UPDATE user_credentials
            SET password_hash = ?, salt = ?, must_change_password = 1, updated_at = ?
            WHERE username = ? AND user_type = ?
        ''', (password_hash, salt, now, username, user_type))
        conn.commit()

    if cursor.rowcount > 0:
        return default_password
    return None

```

```

def find_user_by_identifier(identifier: str) -> dict

```

Find a user by email or username across all user types. Returns user info including user_type if found. Also checks if identifier matches super_admin.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `identifier: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.

- **return type annotation** — Annotated return type -> dict. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **if** `identifier.lower()` in `['super_admin', 'superadmin', 'admin']`: branches conditionally.
2. **if** `identifier.lower()` in `['bef_admin', 'befadmin', 'bef']`: branches conditionally.
3. **if** `identifier.lower()` in `['kwok_admin', 'kwokadmin', 'kwok', 'showcase...']`: branches conditionally.
4. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```
def find_user_by_identifier(identifier: str) -> dict:
    """
    Find a user by email or username across all user types.
    Returns user info including user_type if found.
    Also checks if identifier matches super_admin.
    """
    # Check if it's super_admin
    if identifier.lower() in ['super_admin', 'superadmin', 'admin']:
        return {'user_type': 'super_admin', 'username': 'super_admin'}

    # Check if it's bef_admin
    if identifier.lower() in ['bef_admin', 'befadmin', 'bef']:
        return {'user_type': 'bef_admin', 'username': 'bef_admin'}

    # Kwok (investor-style) dashboard – full read access, no writes (enforced in app)
    if identifier.lower() in [
        'kwok_admin', 'kwokadmin', 'kwok',
        'showcase_admin', 'showcaseadmin', 'showcase', 'investor_demo',
        'investor', 'demo_investor',
    ]:
        return {'user_type': 'kwok_admin', 'username': 'kwok_admin'}

    with get_connection() as conn:
        cursor = conn.cursor()
        # Search by username or email across all user types
        cursor.execute('''
            SELECT id, username, email, user_type, parent_admin, parent_trader,
                   is_active, must_change_password, password_hash, salt, last_login
            FROM user_credentials
            WHERE (username = ? OR email = ?) AND is_active = 1
            ''', (identifier, identifier))
        row = cursor.fetchone()
        return dict(row) if row else None

def verify_user_by_identifier(identifier: str, password: str) -> dict:
    """
    Verify user credentials by email or username (auto-detect user type). Returns user info with user_type if
    successful, None otherwise.
    """
```

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., identifier: str, password: str). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type -> dict. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. Assigns user = find_user_by_identifier(identifier).
2. if not user: branches conditionally.
3. if user.get('user_type') in ('super_admin', 'bef_admin', 'kwok_admin'): branches conditionally.
4. Assigns stored_hash = user.get('password_hash').
5. Assigns salt = user.get('salt').
6. if not stored_hash or not salt: branches conditionally.
7. Assigns password_hash = hashlib.pbkdf2_hmac('sha256', password.encode(), salt.enc....
8. if password_hash == stored_hash: branches conditionally.
9. return None.

Code (copy-paste safe)

```
def verify_user_by_identifier(identifier: str, password: str) -> dict:
    """
    Verify user credentials by email or username (auto-detect user type).
    Returns user info with user_type if successful, None otherwise.
    """
    user = find_user_by_identifier(identifier)
    if not user:
        return None

    # Super admin and BEF admin have special handling
    if user.get('user_type') in ('super_admin', 'bef_admin', 'kwok_admin'):
        return user # Password check happens separately

    # Verify password for regular users
    stored_hash = user.get('password_hash')
    salt = user.get('salt')

    if not stored_hash or not salt:
        return None

    password_hash = hashlib.pbkdf2_hmac('sha256', password.encode(), salt.encode(), 100000).hex()

    if password_hash == stored_hash:
        # Update last login
        with get_connection() as conn:
            cursor = conn.cursor()
            cursor.execute(
                'UPDATE user_credentials SET last_login = ? WHERE id = ?',
```

```

        (datetime.now().isoformat(), user['id'])
    )
    conn.commit()

    # Remove sensitive data before returning
    user.pop('password_hash', None)
    user.pop('salt', None)
    return user

return None

def delete_user_credential(username: str, user_type: str) -> bool

```

Permanently delete a user credential.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `username: str, user_type: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> bool`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```

def delete_user_credential(username: str, user_type: str) -> bool:
    """Permanently delete a user credential."""
    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute(''
            DELETE FROM user_credentials
            WHERE username = ? AND user_type = ?
            ''', (username, user_type))
        conn.commit()
        return cursor.rowcount > 0

def update_user_email(username: str, user_type: str, new_email: str) -> bool

```

Update a user's email address.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `username: str, user_type: str, new_email: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> bool`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```
def update_user_email(username: str, user_type: str, new_email: str) -> bool:
    """Update a user's email address."""
    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute('''
            UPDATE user_credentials
            SET email = ?, updated_at = ?
            WHERE username = ? AND user_type = ?
        ''', (new_email, datetime.now().isoformat(), username, user_type))
        conn.commit()
        return cursor.rowcount > 0

def rename_user_credential(old_name: str, new_name: str, user_type: str) -> bool
    Rename a user in user_credentials table.
```

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `old_name: str`, `new_name: str`, `user_type: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> bool`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```
def rename_user_credential(old_name: str, new_name: str, user_type: str) -> bool:
    """Rename a user in user_credentials table."""
    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute('''
            UPDATE user_credentials SET username = ?, updated_at = ?
            WHERE username = ? AND user_type = ?
        ''', (new_name, datetime.now().isoformat(), old_name, user_type))
        conn.commit()
        return cursor.rowcount > 0

def rename_client_in_db(old_name: str, new_name: str) -> bool
    Rename client_id across all client data tables.
```

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `old_name: str`, `new_name: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> bool`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```
def rename_client_in_db(old_name: str, new_name: str) -> bool:
    """Rename client_id across all client data tables."""
    with get_connection() as conn:
        cursor = conn.cursor()
        for table in ['clients_data', 'data_history', 'cell_notes', 'daily_watermarks', 'waterlog_periods']:
            try:
                cursor.execute(f'UPDATE {table} SET client_id = ? WHERE client_id = ?', (new_name, old_name))
            except Exception:
                pass
        conn.commit()
    return True
```

```
def user_exists(username: str, user_type: str) -> bool
```

Check if a user already exists.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `username: str`, `user_type: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> bool`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```
def user_exists(username: str, user_type: str) -> bool:
    """Check if a user already exists."""
    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute(
            'SELECT 1 FROM user_credentials WHERE username = ? AND user_type = ?',
            (username, user_type)
        )
        return cursor.fetchone() is not None

def record_login_attempt(username: str, user_type: str, ip_address: str, success: bool)
    Record a login attempt.
```

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `username: str`, `user_type: str`, `ip_address: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **with-statement** — Uses a `with` block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. `with get_connection():` enters a context manager.

Code (copy-paste safe)

```
def record_login_attempt(username: str, user_type: str, ip_address: str, success: bool):
    """Record a login attempt."""
    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute('''
            INSERT INTO login_attempts (username, user_type, ip_address, attempt_time, success)
            VALUES (?, ?, ?, ?, ?)
            ''', (username, user_type, ip_address, datetime.now().isoformat(), 1 if success else 0))
        conn.commit()

def get_failed_login_count(username: str, user_type: str, minutes: int=15) -> int
    Get count of failed login attempts in the last X minutes.
```

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `username: str`, `user_type: str`, `minutes: int`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> int`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Lazy import from `datetime`.
2. Assigns `cutoff = (datetime.now() - timedelta(minutes=minutes)).isoformat()`.
3. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```
def get_failed_login_count(username: str, user_type: str, minutes: int = 15) -> int:
    """Get count of failed login attempts in the last X minutes."""
    from datetime import timedelta
    cutoff = (datetime.now() - timedelta(minutes=minutes)).isoformat()

    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute('''
            SELECT COUNT(*) as count FROM login_attempts
            WHERE username = ? AND user_type = ? AND success = 0 AND attempt_time > ?
        ''', (username, user_type, cutoff))
        row = cursor.fetchone()
        return row['count'] if row else 0

def is_account_locked(username: str, user_type: str, max_attempts: int=5) -> bool
    Check if account is locked due to too many failed attempts.
```

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `username: str`, `user_type: str`, `max_attempts: int`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> bool`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. **return** `get_failed_login_count(username, user_type) >= max_attempts`.

Code (copy-paste safe)

```
def is_account_locked(username: str, user_type: str, max_attempts: int = 5) -> bool:
    """Check if account is locked due to too many failed attempts."""
    return get_failed_login_count(username, user_type) >= max_attempts

def hash_api_key(api_key: str) -> str
    Hash an API key using SHA-256.
```

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `api_key: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.

- **return type annotation** — Annotated return type `-> str`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. `return hashlib.sha256(api_key.encode('utf-8')).hexdigest()`.

Code (copy-paste safe)

```
def hash_api_key(api_key: str) -> str:
    """Hash an API key using SHA-256."""
    return hashlib.sha256(api_key.encode('utf-8')).hexdigest()

def generate_api_key(admin: str, trader: str, client: str='', scope: str='full') -> str:
    Generate a new API key and store its hash. scope: 'full' for full access, 'readonly' for read-only endpoints only.
```

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `admin: str, trader: str, client: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.

- **return type annotation** — Annotated return type `-> str`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `api_key = 'tk_' + secrets.token_urlsafe(32)`.
2. Assigns `key_hash = hash_api_key(api_key)`.
3. Assigns `key_prefix = api_key[:12]`.
4. Assigns `now = datetime.now().isoformat()`.
5. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```
def generate_api_key(admin: str, trader: str, client: str = '', scope: str = 'full') -> str:
    """Generate a new API key and store its hash.

    scope: 'full' for full access, 'readonly' for read-only endpoints only.
    """
```

```

api_key = 'tk_' + secrets.token_urlsafe(32)
key_hash = hash_api_key(api_key)
key_prefix = api_key[:12] # Store prefix for identification
now = datetime.now().isoformat()

with get_connection() as conn:
    cursor = conn.cursor()
    try:
        cursor.execute('''
            INSERT INTO api_keys (key_hash, key_prefix, admin, trader, client, scope, created_at)
            VALUES (?, ?, ?, ?, ?, ?, ?)
        ''', (key_hash, key_prefix, admin, trader, client, scope, now))
        conn.commit()
        return api_key # Return the actual key (only time it's visible)
    except Exception as e:
        print(f"Error generating API key: {e}")
        return None

```

```
def validate_api_key(api_key: str) -> dict
```

Validate an API key and return user info if valid. Includes 'scope' in the result.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `api_key: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> dict`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. Assigns `key_hash = hash_api_key(api_key)`.
2. `with get_connection()`: enters a context manager.

Code (copy-paste safe)

```

def validate_api_key(api_key: str) -> dict:
    """Validate an API key and return user info if valid. Includes 'scope' in the result."""
    key_hash = hash_api_key(api_key)

    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute('''
            SELECT admin, trader, client, scope, created_at FROM api_keys
            WHERE key_hash = ? AND is_active = 1
        ''', (key_hash,))
        row = cursor.fetchone()

    if row:
        # Update last_used timestamp
        cursor.execute(
            'UPDATE api_keys SET last_used = ? WHERE key_hash = ?',
            (datetime.now().isoformat(), key_hash)
        )

```

```

        conn.commit()

    return {
        'admin': row['admin'],
        'trader': row['trader'],
        'client': row['client'],
        'scope': row['scope'] or 'full',
        'created': row['created_at']
    }

return None

```

```
def list_api_keys() -> list
```

List all API keys (showing only prefix).

Why these Python concepts were used

- **return type annotation** — Annotated return type `-> list`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.

Step by step (top-level body)

1. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```

def list_api_keys() -> list:
    """List all API keys (showing only prefix)."""
    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute('''
            SELECT key_prefix, admin, trader, client, scope, created_at, last_used, is_active
            FROM api_keys ORDER BY created_at DESC
        ''')
    return [dict(row) for row in cursor.fetchall()]

```

```
def revoke_api_key(key_prefix: str) -> bool
```

Revoke an API key by its prefix.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `key_prefix: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> bool`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```
def revoke_api_key(key_prefix: str) -> bool:
    """Revoke an API key by its prefix."""
    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute(
            'UPDATE api_keys SET is_active = 0 WHERE key_prefix = ?',
            (key_prefix,)
        )
        conn.commit()
        return cursor.rowcount > 0
```

```
def delete_api_key(key_prefix: str) -> bool
```

Permanently delete an API key by its prefix.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `key_prefix: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> bool`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```
def delete_api_key(key_prefix: str) -> bool:
    """Permanently delete an API key by its prefix."""
    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute('DELETE FROM api_keys WHERE key_prefix = ?', (key_prefix,))
        conn.commit()
        return cursor.rowcount > 0
```

```
def add_kyc_link(primary_client: str, linked_client: str, linked_by: str='super_admin') -> bool
```

Link a secondary client account to a primary client as a KYC.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `primary_client: str`, `linked_client: str`, `linked_by: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.

- **return type annotation** — Annotated return type -> bool. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. **if** `primary_client == linked_client`: branches conditionally.
2. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```
def add_kyc_link(primary_client: str, linked_client: str, linked_by: str = 'super_admin') -> bool:
    """Link a secondary client account to a primary client as a KYC."""
    if primary_client == linked_client:
        return False
    with get_connection() as conn:
        cursor = conn.cursor()
        try:
            cursor.execute('''
                INSERT INTO kyc_links (primary_client, linked_client, linked_by, created_at)
                VALUES (?, ?, ?, ?)
            ''', (primary_client, linked_client, linked_by, datetime.now().isoformat()))
            conn.commit()
            return True
        except psycopg2.IntegrityError:
            conn.rollback()
            return False
```

```
def remove_kyc_link(primary_client: str, linked_client: str) -> bool
```

Remove a KYC link between two clients.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `primary_client: str`, `linked_client: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type -> bool. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```
def remove_kyc_link(primary_client: str, linked_client: str) -> bool:
    """Remove a KYC link between two clients."""
    with get_connection() as conn:
```

```

cursor = conn.cursor()
cursor.execute('DELETE FROM kyc_links WHERE primary_client = ? AND linked_client = ?',
               (primary_client, linked_client))
conn.commit()
return cursor.rowcount > 0

```

```
def get_kyc_linked_clients(primary_client: str) -> list
```

Get all linked KYC accounts for a primary client.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `primary_client: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> list`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.

Step by step (top-level body)

1. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```

def get_kyc_linked_clients(primary_client: str) -> list:
    """Get all linked KYC accounts for a primary client."""
    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute('SELECT linked_client, linked_by, created_at FROM kyc_links WHERE primary_client = '
                       '(primary_client,))
        return [{'linked_client': r['linked_client'], 'linked_by': r['linked_by'],
                  'created_at': r['created_at']} for r in cursor.fetchall()]

```

```
def get_kyc_primary_for(linked_client: str) -> str
```

If this client is linked to someone, return the primary client name.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `linked_client: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> str`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```
def get_kyc_primary_for(linked_client: str) -> str:
    """If this client is linked to someone, return the primary client name."""
    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute('SELECT primary_client FROM kyc_links WHERE linked_client = ?',
                        (linked_client,))
        row = cursor.fetchone()
        return row['primary_client'] if row else None
```

```
def is_kyc_primary(client_name: str) -> bool
```

Check if this client is a primary KYC account (has linked accounts under it).

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `client_name: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> bool`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. **return** `len(get_kyc_linked_clients(client_name)) > 0`.

Code (copy-paste safe)

```
def is_kyc_primary(client_name: str) -> bool:
    """Check if this client is a primary KYC account (has linked accounts under it)."""
    return len(get_kyc_linked_clients(client_name)) > 0
```

```
def get_all_kyc_accounts(client_name: str) -> list
```

Get all KYC accounts for a client (including self). If client_name is primary → returns [self] + linked accounts. If client_name is linked → returns [primary] + all siblings + self.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `client_name: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> list`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with `append`, and clearer about intent: this is a transform, not a side-effecting loop.

Step by step (top-level body)

1. Assigns `linked = get_kyc_linked_clients(client_name)`.

2. **if** linked: branches conditionally.
3. Assigns `primary = get_kyc_primary_for(client_name)`.
4. **if** primary: branches conditionally.
5. **return** `[client_name]`.

Code (copy-paste safe)

```
def get_all_kyc_accounts(client_name: str) -> list:
    """Get all KYC accounts for a client (including self).
    If client_name is primary → returns [self] + linked accounts.
    If client_name is linked → returns [primary] + all siblings + self.
    """
    # Check if this client is a primary
    linked = get_kyc_linked_clients(client_name)
    if linked:
        return [client_name] + [l['linked_client'] for l in linked]
    # Check if this client is linked to a primary
    primary = get_kyc_primary_for(client_name)
    if primary:
        siblings = get_kyc_linked_clients(primary)
        return [primary] + [l['linked_client'] for l in siblings]
    return [client_name]
```

```
def get_all_kyc_links() -> list
```

Get all KYC links in the system (for admin view).

Why these Python concepts were used

- **return type annotation** — Annotated return type `-> list`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with `append`, and clearer about intent: this is a transform, not a side-effecting loop.

Step by step (top-level body)

1. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```
def get_all_kyc_links() -> list:
    """Get all KYC links in the system (for admin view)."""
    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute(
            'SELECT primary_client, linked_client, linked_by, created_at FROM kyc_links ORDER BY primary'
        )
        return [dict(r) for r in cursor.fetchall()]
```

```
def save_client_data(client_id: str, data: dict, overwrite: bool=False) -> bool
```

Save client data to database. If `overwrite=True`, replaces all existing data with the provided data (used for sheet imports). If `overwrite=False` (default), merges: new values take precedence but missing keys fall

back to existing.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `client_id: str`, `data: dict`, `overwrite: bool`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> bool`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **dict comprehension** — Builds a dict in one expression (`{k: v for k, v in items}`) — same intent as a list comprehension but for mappings.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns `now = datetime.now().isoformat()`.
2. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```
def save_client_data(client_id: str, data: dict, overwrite: bool = False) -> bool:
    """Save client data to database.

    If overwrite=True, replaces all existing data with the provided data (used for sheet imports).
    If overwrite=False (default), merges: new values take precedence but missing keys fall back to existing.
    """

```

```
def get_client_data(client_id: str) -> dict
```

Get client data from database.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `client_id: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> dict`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```
def get_client_data(client_id: str) -> dict:
    """Get client data from database."""
    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute('SELECT * FROM clients_data WHERE client_id = ?', (client_id,))
        row = cursor.fetchone()

    if row:
        try:
            identity = json.loads(row['identity'] or '{}') or {}
        except Exception:
            identity = {}
        return {
            'deals': json.loads(row['deals']),
            'positions': json.loads(row['positions']),
            'account': json.loads(row['account']),
            'evaluations': json.loads(row['evaluations']),
            'statistics': json.loads(row['statistics']),
            'dropdown_options': json.loads(row['dropdown_options']),
            'identity': identity,
            'sheet_url': identity.get('sheet_url') if isinstance(identity, dict) else None,
            'last_updated': row['last_updated'],
            'hedge_accounts': json.loads(row.get('hedge_accounts') or '[]'),
            'prop_accounts': json.loads(row.get('prop_accounts') or '[]'),
            'vps_accounts': json.loads(row.get('vps_accounts') or '[]'),
            'payment_info': json.loads(row.get('payment_info') or '[]'),
            'payment_address': json.loads(row.get('payment_address') or '{}'),
            'mt5_credentials': json.loads(row.get('mt5_credentials') or '{}'),
```

```

        'firm_billing': json.loads(row.get('firm_billing') or '{}'),
    }

    return None

```

```
def get_all_clients() -> dict
```

Get all client data in a single query (avoids N+1 pattern).

Why these Python concepts were used

- **return type annotation** — Annotated return type -> dict. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **with get_connection():** enters a context manager.

Code (copy-paste safe)

```

def get_all_clients() -> dict:
    """Get all client data in a single query (avoids N+1 pattern)."""
    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute('SELECT * FROM clients_data')
        clients = {}
        for row in cursor.fetchall():
            client_id = row['client_id']
            try:
                identity = json.loads(row['identity'] or '{}') or {}
            except Exception:
                identity = {}
            clients[client_id] = {
                'deals': json.loads(row['deals']),
                'positions': json.loads(row['positions']),
                'account': json.loads(row['account']),
                'evaluations': json.loads(row['evaluations']),
                'statistics': json.loads(row['statistics']),
                'dropdown_options': json.loads(row['dropdown_options']),
                'identity': identity,
                'sheet_url': identity.get('sheet_url') if isinstance(identity, dict) else None,
                'last_updated': row['last_updated'],

                'prop_accounts': json.loads(row.get('prop_accounts') or '[]'),
                'vps_accounts': json.loads(row.get('vps_accounts') or '[]'),
                'payment_info': json.loads(row.get('payment_info') or '[]'),
                'payment_address': json.loads(row.get('payment_address') or '{}'),
            }

```

```

        'mt5_credentials': json.loads(row.get('mt5_credentials') or '{}'),
        'firm_billing': json.loads(row.get('firm_billing') or '{}'),
    }
    return clients

```

```
def get_all_client_identities() -> dict
```

Fetch only client_id + identity for all clients in one query. Used to avoid N+1 queries when only identity fields are needed.

Why these Python concepts were used

- **return type annotation** — Annotated return type -> dict. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```

def get_all_client_identities() -> dict:
    """Fetch only client_id + identity for all clients in one query.
    Used to avoid N+1 queries when only identity fields are needed."""
    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute('SELECT client_id, identity FROM clients_data')
        result = {}
        for row in cursor.fetchall():
            try:
                identity = json.loads(row['identity'] or '{}') or {}
            except Exception:
                identity = {}
            result[row['client_id']] = identity
        return result

```

```
def delete_client_data(client_id: str) -> bool
```

Permanently delete all data for a client from the database.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `client_id: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type -> bool. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```
def delete_client_data(client_id: str) -> bool:
    """Permanently delete all data for a client from the database."""
    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute('DELETE FROM clients_data WHERE client_id = ?', (client_id,))
        cursor.execute('DELETE FROM data_history WHERE client_id = ?', (client_id,))
        cursor.execute('DELETE FROM cell_notes WHERE client_id = ?', (client_id,))
        cursor.execute('DELETE FROM daily_watermarks WHERE client_id = ?', (client_id,))
        cursor.execute('DELETE FROM waterlog_periods WHERE client_id = ?', (client_id,))
        conn.commit()
        return cursor.rowcount >= 0

def get_clients_count() -> int
    Get count of clients in database.
```

Why these Python concepts were used

- **return type annotation** — Annotated return type `-> int`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```
def get_clients_count() -> int:
    """Get count of clients in database."""
    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute('SELECT COUNT(*) as count FROM clients_data')
        row = cursor.fetchone()
        return row['count'] if row else 0

def update_client_field(client_id: str, field: str, value) -> bool
    Update a specific field for a client.
```

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `client_id: str`, `field: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> bool`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `valid_fields = ['deals', 'positions', 'account', 'evaluations', 'statist...`
2. **if** `field not in valid_fields`: branches conditionally.
3. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```
def update_client_field(client_id: str, field: str, value) -> bool:
    """Update a specific field for a client."""
    valid_fields = ['deals', 'positions', 'account', 'evaluations', 'statistics', 'identity',
                    'dropdown_options',
                    'hedge_accounts', 'prop_accounts', 'vps_accounts', 'payment_info', 'payment_address']
    if field not in valid_fields:
        return False

    with get_connection() as conn:
        cursor = conn.cursor()

        # First ensure client exists
        cursor.execute('SELECT client_id FROM clients_data WHERE client_id = ?', (client_id,))
        if cursor.fetchone() is None:
            # Create new client record
            save_client_data(client_id, {field: value})
            return True

        # Update specific field
        cursor.execute(f'''
            UPDATE clients_data
            SET {field} = ?, last_updated = ?
            WHERE client_id = ?
        ''', (json.dumps(value), datetime.now().isoformat(), client_id))
        conn.commit()
        return True
```

```
def _repair_quality_table()
```

No-op — schema is managed by Alembic. PostgreSQL handles table integrity.

Step by step (top-level body)

1. Calls `print(...)` for its side effect.

Code (copy-paste safe)

```
def _repair_quality_table():
    """No-op — schema is managed by Alembic. PostgreSQL handles table integrity."""
    print("[DB] quality_scan_results table integrity is managed by PostgreSQL")
```

```
def save_quality_scan_results(scan_date: str, results: list)
```

Save quality scan results for all clients.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `scan_date: str`, `results: list`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **raise** — Raises an exception explicitly. Either signals an invalid argument the caller should fix, or re-raises after logging.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def save_quality_scan_results(scan_date: str, results: list):
    """Save quality scan results for all clients."""
    try:
        with get_connection() as conn:
            cursor = conn.cursor()
            cursor.execute('DELETE FROM quality_scan_results WHERE scan_date = ?', (scan_date,))
            for r in results:
                cursor.execute('''
                    INSERT INTO quality_scan_results (scan_date, client_id, trader, admin, total_issues,
                        issues, health_score)
                    VALUES (?, ?, ?, ?, ?, ?, ?)
                ''', (scan_date, r['client_id'], r.get('trader'), r.get('admin'),
                    r['total_issues'], json.dumps(r['issues']), r['health_score']))
            conn.commit()
    except Exception as e:
        print(f"Error saving quality scan results: {e}")
        raise
```

```
def get_quality_scan_results(scan_date: str=None) -> list
```

Get quality scan results. If no date, returns latest scan.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `scan_date: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> list`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't

have to handle it.

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def get_quality_scan_results(scan_date: str = None) -> list:
    """Get quality scan results. If no date, returns latest scan."""
    try:
        return _get_quality_scan_results_inner(scan_date)
    except Exception as e:
        print(f"Error getting quality scan results: {e}")
        return []
```

```
def _get_quality_scan_results_inner(scan_date: str=None) -> list
```

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `scan_date: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> list`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```
def _get_quality_scan_results_inner(scan_date: str = None) -> list:
    with get_connection() as conn:
        cursor = conn.cursor()
        if not scan_date:
            cursor.execute('SELECT MAX(scan_date) as d FROM quality_scan_results')
            row = cursor.fetchone()
            scan_date = row['d'] if row and row['d'] else None
        if not scan_date:
            return []
        cursor.execute('''
            SELECT * FROM quality_scan_results WHERE scan_date = ? ORDER BY health_score ASC
        ''', (scan_date,))
        results = []
        for row in cursor.fetchall():
            results.append({
                'client_id': row['client_id'],
                'trader': row['trader'],
                'admin': row['admin'],
```

```

        'total_issues': row['total_issues'],
        'issues': json.loads(row['issues']),
        'health_score': row['health_score'],
        'scan_date': row['scan_date'],
    })
    return results

```

```

def save_daily_checklist(date: str, user_identifier: str, user_type: str, checklist_type: str, items: list,
                        ip_address: str=None, client_id: str='')

```

Save a daily checklist submission (per client).

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `date: str`, `user_identifier: str`, `user_type: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.

- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```

def save_daily_checklist(date: str, user_identifier: str, user_type: str,
                        checklist_type: str, items: list, ip_address: str = None,
                        client_id: str = ''):
    """Save a daily checklist submission (per client)."""
    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute('''
            INSERT INTO daily_checklists (date, user_identifier, user_type, checklist_type, client_id, ip_address,
            submitted_at, ip_address)
            VALUES (?, ?, ?, ?, ?, ?, ?, ?)
            ON CONFLICT(date, user_identifier, checklist_type, client_id) DO UPDATE SET
                user_type = excluded.user_type,
                items = excluded.items,
                submitted_at = excluded.submitted_at,
                ip_address = excluded.ip_address
        ''', (date, user_identifier, user_type, checklist_type, client_id, json.dumps(items),
            datetime.now().isoformat(), ip_address))
        conn.commit()

```

```

def _ensure_checklist_client_column()

```

No-op — schema is managed by Alembic.

Step by step (top-level body)

1. **pass** (placeholder).

Code (copy-paste safe)

```

def _ensure_checklist_client_column():
    """No-op – schema is managed by Alembic."""

```

```
pass
```

```
def _ensure_settings_table()
```

No-op — schema is managed by Alembic.

Step by step (top-level body)

1. **pass** (placeholder).

Code (copy-paste safe)

```
def _ensure_settings_table():
    """No-op — schema is managed by Alembic."""
    pass
```

```
def get_setting(key: str) -> str
```

Get a system setting by key. Returns empty string if not found.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `key: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> str`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def get_setting(key: str) -> str:
    """Get a system setting by key. Returns empty string if not found."""
    try:
        with get_connection() as conn:
            cursor = conn.cursor()
            cursor.execute('SELECT value FROM system_settings WHERE key = ?', (key,))
            row = cursor.fetchone()
            return row['value'] if row else ''
    except Exception:
        _ensure_settings_table()
        return ''
```

```
def set_setting(key: str, value: str, updated_by: str='')
```

Set a system setting.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `key: str, value: str, updated_by: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. Calls `_ensure_settings_table(...)` for its side effect.
2. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```
def set_setting(key: str, value: str, updated_by: str = ''):
    """Set a system setting."""
    _ensure_settings_table()
    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute('''
            INSERT INTO system_settings (key, value, updated_at, updated_by)
            VALUES (?, ?, ?, ?)
            ON CONFLICT(
                key) DO UPDATE SET value=excluded.value, updated_at=excluded.updated_at, updated_by=exc
            ''', (key, value, datetime.now().isoformat(), updated_by))
        conn.commit()
```

```
def get_daily_checklists(date: str, user_identifier: str=None) -> list
```

Get checklists for a date, optionally filtered by user.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `date: str, user_identifier: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> list`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **list comprehension** — Builds a list in a single expression `[f(x) for x in xs]`. Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```
def get_daily_checklists(date: str, user_identifier: str = None) -> list:
    """Get checklists for a date, optionally filtered by user."""
    with get_connection() as conn:
        cursor = conn.cursor()
        if user_identifier:
            cursor.execute('SELECT * FROM daily_checklists WHERE date = ? AND user_identifier = ?',
                           (date, user_identifier))
        else:
            cursor.execute('SELECT * FROM daily_checklists WHERE date = ?', (date,))
    return [{
        'user_identifier': row['user_identifier'],
        'user_type': row['user_type'],
        'checklist_type': row['checklist_type'],
        'client_id': row['client_id'] if 'client_id' in row.keys() else '',
        'items': json.loads(row['items']),
        'submitted_at': row['submitted_at'],
    } for row in cursor.fetchall()]
```

```
def get_checklist_clients_for_date(date: str) -> set
```

Return set of client_ids that have a daily_summary checklist submitted for the given date.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `date: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> set`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **set comprehension** — Builds a set in one expression — usually to deduplicate the result of a transform.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def get_checklist_clients_for_date(date: str) -> set:
    """Return set of client_ids that have a daily_summary checklist submitted for the given date."""
    try:
        with get_connection() as conn:
            cursor = conn.cursor()
            cursor.execute(
                'SELECT DISTINCT client_id FROM daily_checklists WHERE date = ? AND checklist_type = 'da
                (date,)
            )
            return {row['client_id'] for row in cursor.fetchall()}
    except Exception:
        return set()
```

```
def get_summary_status_for_date(date: str) -> list
```

Return all daily_summary checklist submissions for the given date. Merges data from daily_checklists table AND audit_log. The 24-hour window runs from 23:05 UTC day-1 to 23:05 UTC day (= 2:05 AM Kenyan → 2:05 AM Kenyan). The `date` parameter is the UTC date (server runs UTC).

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., date: str). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type -> list. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. Assigns results = {}.
2. Lazy import from datetime.
3. **try** block with 1 **except** clause.
4. Assigns utc_start = (utc_date - _td(days=1)).strftime('%Y-%m-%d') + 'T23:05'.
5. Assigns utc_end = utc_date.strftime('%Y-%m-%d') + 'T23:05'.
6. **try** block with 1 **except** clause.
7. **return** list(results.values()).

Code (copy-paste safe)

```
def get_summary_status_for_date(date: str) -> list:
    """Return all daily_summary checklist submissions for the given date.
    Merges data from daily_checklists table AND audit_log.

    The 24-hour window runs from 23:05 UTC day-1 to 23:05 UTC day
    (= 2:05 AM Kenyan → 2:05 AM Kenyan). The `date` parameter is the
    UTC date (server runs UTC).
    """

except Exception:
    pass
return list(results.values())

```

```
def get_weekly_scan_results(end_date: str=None, days: int=7) -> list
```

Get quality scan results for a date range (default: last 7 days).

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `end_date: str`, `days: int`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> list`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def get_weekly_scan_results(end_date: str = None, days: int = 7) -> list:
    """Get quality scan results for a date range (default: last 7 days)."""
    try:
        return _get_weekly_scan_results_inner(end_date, days)
    except Exception as e:
        print(f"Error getting weekly scan results: {e}")
        return []
```

```
def _get_weekly_scan_results_inner(end_date: str=None, days: int=7) -> list
```

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `end_date: str`, `days: int`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> list`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```
def _get_weekly_scan_results_inner(end_date: str = None, days: int = 7) -> list:
    with get_connection() as conn:
        cursor = conn.cursor()
        if not end_date:
            end_date = datetime.now().strftime('%Y-%m-%d')
        start_date = (datetime.strptime(end_date, '%Y-%m-%d') - timedelta(days=days - 1)).strftime('%Y-%m-%d')
        cursor.execute('''
            SELECT * FROM quality_scan_results
            WHERE scan_date BETWEEN ? AND ?
            ORDER BY scan_date ASC, health_score ASC
        ''', (start_date, end_date))
        results = []
        for row in cursor.fetchall():
            results.append({
                'client_id': row['client_id'],
                'trader': row['trader'],
                'admin': row['admin'],
                'total_issues': row['total_issues'],
                'issues': json.loads(row['issues']),
                'health_score': row['health_score'],
                'scan_date': row['scan_date'],
            })
```

```
return results
```

```
def _ensure_qa_resolutions_table()
```

Ensure QA resolution table exists (small operational table).

Why these Python concepts were used

- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```
def _ensure_qa_resolutions_table():
    """Ensure QA resolution table exists (small operational table)."""
    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute('''
            CREATE TABLE IF NOT EXISTS qa_resolutions (
                check_name TEXT NOT NULL,
                client_id TEXT NOT NULL,
                row_index INTEGER NOT NULL,
                resolved BOOLEAN NOT NULL DEFAULT TRUE,
                resolved_by TEXT NOT NULL DEFAULT '',
                resolved_at TEXT NOT NULL,
                notes TEXT NOT NULL DEFAULT '',
                PRIMARY KEY (check_name, client_id, row_index)
            )
        ''')
        conn.commit()
```

```
def get_qa_resolved_set(check_name: str) -> set
```

Return a set of (client_id, row_index) resolved for a given QA check.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `check_name: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> set`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. **if** `not check_name`: branches conditionally.

2. try block with 1 except clause.

Code (copy-paste safe)

```
def get_qa_resolved_set(check_name: str) -> set:
    """Return a set of (client_id, row_index) resolved for a given QA check."""
    if not check_name:
        return set()
    try:
        _ensure_qa_resolutions_table()
        with get_connection() as conn:
            cursor = conn.cursor()
            cursor.execute(
                'SELECT client_id, row_index FROM qa_resolutions WHERE check_name = ? AND resolved = TRUE'
                (check_name,)
            )
            rows = cursor.fetchall() or []
            out = set()
            for r in rows:
                try:
                    out.add((r['client_id'], int(r['row_index'])))
                except Exception:
                    continue
            return out
    except Exception:
        return set()
```

```
def is_qa_resolved(check_name: str, client_id: str, row_index: int) -> bool
```

Check whether a specific QA issue has been resolved.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `check_name: str`, `client_id: str`, `row_index: int`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> bool`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. **if not check_name or not client_id:** branches conditionally.
2. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def is_qa_resolved(check_name: str, client_id: str, row_index: int) -> bool:
    """Check whether a specific QA issue has been resolved."""
    if not check_name or not client_id:
        return False
```

```

try:
    _ensure_qa_resolutions_table()
    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute(
            'SELECT resolved FROM qa_resolutions WHERE check_name = ? AND client_id = ? AND row_index = ?'
            (check_name, client_id, int(row_index))
        )
        row = cursor.fetchone()
        return bool(row and row.get('resolved'))
except Exception:
    return False

```

```
def mark_qa_resolved(check_name: str, client_id: str, row_index: int, resolved_by: str, notes: str=''):
```

Mark a QA issue resolved (idempotent).

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `check_name: str`, `client_id: str`, `row_index: int`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. **if** not `check_name` or not `client_id`: branches conditionally.
2. Calls `_ensure_qa_resolutions_table(...)` for its side effect.
3. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```

def mark_qa_resolved(check_name: str, client_id: str, row_index: int, resolved_by: str, notes: str = ''):
    """Mark a QA issue resolved (idempotent)."""
    if not check_name or not client_id:
        return
    _ensure_qa_resolutions_table()
    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute('''
            INSERT INTO qa_resolutions (check_name, client_id, row_index, resolved, resolved_by, resolved_at,
            notes)
            VALUES (?, ?, ?, TRUE, ?, ?, ?)
            ON CONFLICT(check_name, client_id, row_index) DO UPDATE SET
                resolved = TRUE,
                resolved_by = excluded.resolved_by,
                resolved_at = excluded.resolved_at,
                notes = excluded.notes
        ''', (check_name, client_id, int(row_index), resolved_by or '', datetime.now().isoformat(), notes))
        conn.commit()

```

```
def get_client_activity(client_id: str) -> dict
```

Get last push time and last edit info for a client from data_history.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `client_id: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> dict`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```
def get_client_activity(client_id: str) -> dict:
    """Get last push time and last edit info for a client from data_history."""
    with get_connection() as conn:
        cursor = conn.cursor()
        # Last push (from companion app / MT5)
        cursor.execute('''
            SELECT created_at, changed_by FROM data_history
            WHERE client_id = ? AND change_source = 'push'
            ORDER BY version DESC LIMIT 1
        ''', (client_id,))
        push_row = cursor.fetchone()

        # Last manual edit (from dashboard)
        cursor.execute('''
            SELECT created_at, changed_by, changed_by_type FROM data_history
            WHERE client_id = ? AND change_source IN ('dashboard_edit', 'dashboard_delete')
            ORDER BY version DESC LIMIT 1
        ''', (client_id,))
        edit_row = cursor.fetchone()

    return {
        'last_push_at': push_row['created_at'] if push_row else None,
        'last_push_by': push_row['changed_by'] if push_row else None,
        'last_edit_at': edit_row['created_at'] if edit_row else None,
        'last_edit_by': edit_row['changed_by'] if edit_row else None,
        'last_edit_by_type': edit_row['changed_by_type'] if edit_row else None,
    }
```

```
def get_next_version(client_id: str) -> int
```

Get the next version number for a client's data history.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `client_id: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.

- **return type annotation** — Annotated return type `-> int`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def get_next_version(client_id: str) -> int:
    """Get the next version number for a client's data history."""
    try:
        with get_connection() as conn:
            cursor = conn.cursor()
            cursor.execute(''
                SELECT MAX(version) as max_version FROM data_history WHERE client_id = ?
            '', (client_id,))
            row = cursor.fetchone()
            return (row['max_version'] or 0) + 1
    except Exception as e:
        print(f"Error getting next version: {e}")
        # Fallback to local timestamp-based ID or just start at 1 if DB read fails?
        # If DB read fails, snapshot will likely fail too, but at least we don't crash the app.
        return 1
```

```
def verify_data_saved(client_id: str, expected_evals_count: int=None, expected_stat_key: str=None) -> bool:
```

Verify that data was actually saved and committed to the database. This is a critical check to detect silent commit failures or connection issues. Pass `expected_evals_count` or `expected_stat_key` to verify specific fields were persisted. Returns: `True` if data is present and matches expected values, `False` otherwise.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `client_id: str`, `expected_evals_count: int`, `expected_stat_key: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> bool`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def verify_data_saved(client_id: str, expected_evals_count: int = None,

    logger.error(traceback.format_exc())
    return (False, -1)

```

```
def get_data_history(client_id: str, limit: int=50) -> list
```

Get the history of all data changes for a client. Returns list of history entries (newest first) with metadata.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `client_id: str`, `limit: int`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> list`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **list comprehension** — Builds a list in a single expression ([f(x) for x in xs]). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.

Step by step (top-level body)

1. **with** get_connection(): enters a context manager.

Code (copy-paste safe)

```
def get_data_history(client_id: str, limit: int = 50) -> list:
    """
    Get the history of all data changes for a client.

    Returns list of history entries (newest first) with metadata.
    """
    with get_connection() as conn:

            'version': row['version'],
            'action': row['action'],
            'changed_by': row['changed_by'],
            'changed_by_type': row['changed_by_type'],
            'change_source': row['change_source'],
            'change_description': row['change_description'],
            'created_at': row['created_at'],
            'data': {
                'deals': json.loads(row['deals']),
                'positions': json.loads(row['positions']),
                'account': json.loads(row['account']),
                'evaluations': json.loads(row['evaluations']),
                'statistics': json.loads(row['statistics']),
                'dropdown_options': json.loads(row['dropdown_options']),
                'identity': json.loads(row['identity'])
            }
        }
    return None

```

```

def rollback_to_version(client_id: str, version: int, rolled_back_by: str=None, rolled_back_by_type: str=None,
    ip_address: str=None) -> tuple

```

Rollback client data to a specific historical version. Creates a new version entry marking this as a rollback. Returns: Tuple of (success: bool, new_version: int)

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `client_id: str`, `version: int`, `rolled_back_by: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> tuple`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `historical = get_data_version(client_id, version)`.
2. **if** not historical: branches conditionally.
3. **return** `save_client_data_with_history(client_id, historical['data'], action....`

Code (copy-paste safe)

```

def rollback_to_version(client_id: str, version: int,
    rolled_back_by: str = None,

```

```

        rolled_back_by_type: str = None,
        ip_address: str = None) -> tuple:
    """
    Rollback client data to a specific historical version.

    Creates a new version entry marking this as a rollback.

    Returns:
        Tuple of (success: bool, new_version: int)
    """
    # Get the historical version data
    historical = get_data_version(client_id, version)
    if not historical:
        return (False, -1)

    # Save as new current data with rollback action
    return save_client_data_with_history(
        client_id,
        historical['data'],
        action='ROLLBACK',
        changed_by=rolled_back_by,
        changed_by_type=rolled_back_by_type,
        ip_address=ip_address,
        change_source='rollback',
        change_description=f'Rolled back to version {version} from {historical["created_at"]}'
    )

```

```
def compare_versions(client_id: str, version1: int, version2: int) -> dict
```

Compare two versions of client data and return differences. Returns dict with changed fields and their old/new values.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `client_id: str`, `version1: int`, `version2: int`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> dict`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.

Step by step (top-level body)

1. Assigns `v1_data = get_data_version(client_id, version1)`.
2. Assigns `v2_data = get_data_version(client_id, version2)`.
3. `if not v1_data or not v2_data`: branches conditionally.
4. Assigns `differences = {'version1': version1, 'version2': version2, 'version1_da...`
5. `for field in ['deals', 'positions', 'account', 'evaluations', 'statist...]`: iterates.
6. `return differences`.

Code (copy-paste safe)

```
def compare_versions(client_id: str, version1: int, version2: int) -> dict:
```

```

"""
Compare two versions of client data and return differences.

Returns dict with changed fields and their old/new values.
"""
v1_data = get_data_version(client_id, version1)
v2_data = get_data_version(client_id, version2)

if not v1_data or not v2_data:
    return None

differences = {
    'version1': version1,
    'version2': version2,
    'version1_date': v1_data['created_at'],
    'version2_date': v2_data['created_at'],
    'changes': {}
}

# Compare each major field
for field in ['deals', 'positions', 'account', 'evaluations', 'statistics']:
    d1 = v1_data['data'].get(field)
    d2 = v2_data['data'].get(field)

    if d1 != d2:
        if isinstance(d1, list) and isinstance(d2, list):
            differences['changes'][field] = {
                'type': 'list',
                'v1_count': len(d1),
                'v2_count': len(d2),
                'changed': True
            }
        elif isinstance(d1, dict) and isinstance(d2, dict):
            # For dicts, find specific key changes
            changed_keys = []
            all_keys = set(d1.keys()) | set(d2.keys())
            for key in all_keys:
                if d1.get(key) != d2.get(key):
                    changed_keys.append(key)
            differences['changes'][field] = {
                'type': 'dict',
                'changed_keys': changed_keys
            }
        else:
            differences['changes'][field] = {
                'type': 'other',
                'changed': True
            }

    return differences

```

```
def get_latest_version(client_id: str) -> int
```

Get the latest version number for a client.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `client_id: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and

human readers. They are the fastest way to make a public function self-explanatory.

- **return type annotation** — Annotated return type `-> int`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```
def get_latest_version(client_id: str) -> int:
    """Get the latest version number for a client."""
    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute('''
            SELECT MAX(version) as max_version FROM data_history WHERE client_id = ?
            ''', (client_id,))
        row = cursor.fetchone()
        return row['max_version'] or 0
```

```
def cleanup_old_history(client_id: str=None, keep_versions: int=10) -> int
```

Clean up old history entries, keeping only the latest N versions per client. Also deletes any history entries older than 30 days regardless of version count. Returns the number of deleted entries.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `client_id: str`, `keep_versions: int`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> int`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.

Step by step (top-level body)

1. Assigns `cutoff = (datetime.now() - timedelta(days=30)).isoformat()`.
2. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```
def cleanup_old_history(client_id: str = None, keep_versions: int = 10) -> int:
    """
    Clean up old history entries, keeping only the latest N versions per client.
    Also deletes any history entries older than 30 days regardless of version count.

    Returns the number of deleted entries.
    """
    cutoff = (datetime.now() - timedelta(days=30)).isoformat()
```

```

with get_connection() as conn:
    cursor = conn.cursor()
    total_deleted = 0

    if client_id:
        clients = [client_id]
    else:
        cursor.execute('SELECT DISTINCT client_id FROM data_history')
        clients = [row['client_id'] for row in cursor.fetchall()]

    for cid in clients:
        # Delete versions beyond keep_versions limit
        cursor.execute('''
            DELETE FROM data_history
            WHERE client_id = ? AND version NOT IN (
                SELECT version FROM data_history
                WHERE client_id = ?
                ORDER BY version DESC
                LIMIT ?
            )
        ''', (cid, cid, keep_versions))
        total_deleted += cursor.rowcount

        # Also delete anything older than 30 days
        cursor.execute('''
            DELETE FROM data_history
            WHERE client_id = ? AND created_at < ?
        ''', (cid, cutoff))
        total_deleted += cursor.rowcount

    conn.commit()
    return total_deleted

```

```
def cleanup_audit_log(keep_days: int=30) -> int
```

Delete audit log entries older than keep_days. Returns count deleted.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `keep_days: int`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> int`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. Assigns `cutoff = (datetime.now() - timedelta(days=keep_days)).isoformat()`.
2. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```

def cleanup_audit_log(keep_days: int = 30) -> int:
    """Delete audit log entries older than keep_days. Returns count deleted."""
    cutoff = (datetime.now() - timedelta(days=keep_days)).isoformat()

```

```

with get_connection() as conn:
    cursor = conn.cursor()
    cursor.execute('DELETE FROM audit_log WHERE timestamp < ?', (cutoff,))
    deleted = cursor.rowcount
    conn.commit()
    return deleted

```

```
def cleanup_database() -> dict
```

Master cleanup: prune data_history, audit_log, and expired sessions. Returns a summary dict of rows deleted per table.

Why these Python concepts were used

- **return type annotation** — Annotated return type `-> dict`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to `sum`, `any`, `all`, or `max` where the intermediate list would be wasted.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.

Step by step (top-level body)

1. Imports logging (lazy import inside the function).
2. Assigns `results = {}`.
3. Assigns `results['data_history'] = cleanup_old_history(keep_versions=10)`.
4. Assigns `results['audit_log'] = cleanup_audit_log(keep_days=30)`.
5. Calls `cleanup_expired_sessions(...)` for its side effect.
6. Assigns `results['sessions'] = 'cleaned'`.
7. Assigns `total = sum((v for v in results.values() if isinstance(v, int)))`.
8. Calls `logging.info(...)` for its side effect.
9. **return** results.

Code (copy-paste safe)

```

def cleanup_database() -> dict:
    """
    Master cleanup: prune data_history, audit_log, and expired sessions.
    Returns a summary dict of rows deleted per table.
    """
    import logging
    results = {}

    results['data_history'] = cleanup_old_history(keep_versions=10)
    results['audit_log'] = cleanup_audit_log(keep_days=30)
    cleanup_expired_sessions()
    results['sessions'] = 'cleaned'

```

```
total = sum(v for v in results.values() if isinstance(v, int))
logging.info(f"Database cleanup complete: {results} ({total} rows deleted)")
return results
```

```
def log_action(action: str, user_type: str, user_identifier: str, ip_address: str=None, details: str=None,
              success: bool=True)
```

Log an action to the audit log.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `action: str`, `user_type: str`, `user_identifier: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```
def log_action(action: str, user_type: str, user_identifier: str,
              ip_address: str = None, details: str = None, success: bool = True):
    """Log an action to the audit log."""
    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute('''
            INSERT INTO audit_log (timestamp, action, user_type, user_identifier, ip_address, details,
                                   success)
            VALUES (?, ?, ?, ?, ?, ?, ?)
        ''', (
            datetime.now().isoformat(),
            action,
            user_type,
            user_identifier,
            ip_address,
            details,
            1 if success else 0
        ))
        conn.commit()
```

```
def get_audit_log(limit: int=100, action_filter: str=None) -> list
```

Get recent audit log entries.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `limit: int`, `action_filter: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.

- **return type annotation** — Annotated return type -> list. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **list comprehension** — Builds a list in a single expression ([f(x) for x in xs]). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **with** get_connection(): enters a context manager.

Code (copy-paste safe)

```
def get_audit_log(limit: int = 100, action_filter: str = None) -> list:
    """Get recent audit log entries."""
    with get_connection() as conn:
        cursor = conn.cursor()

        if action_filter:
            cursor.execute('''
                SELECT * FROM audit_log
                WHERE action LIKE ?
                ORDER BY timestamp DESC LIMIT ?
            ''', (f'%{action_filter}%', limit))
        else:
            cursor.execute(
                'SELECT * FROM audit_log ORDER BY timestamp DESC LIMIT ?',
                (limit,)
            )

        return [dict(row) for row in cursor.fetchall()]
```

```
def create_session(user_type: str, user_identifier: str, ip_address: str=None, hours_valid: int=24) -> str:
    """Create a new session token.
```

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., user_type: str, user_identifier: str, ip_address: str). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type -> str. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. Assigns user_identifier = user_identifier.strip().
2. Assigns session_token = secrets.token_urlsafe(32).

3. Assigns `now = datetime.now()`.
4. Assigns `expires = now + timedelta(hours=hours_valid)`.
5. **with** `get_connection()`: enters a context manager.
6. **return** `session_token`.

Code (copy-paste safe)

```
def create_session(user_type: str, user_identifier: str, ip_address: str = None,
                  hours_valid: int = 24) -> str:
    """Create a new session token."""
    user_identifier = user_identifier.strip()
    session_token = secrets.token_urlsafe(32)
    now = datetime.now()
    expires = now + timedelta(hours=hours_valid)

    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute('''
            INSERT INTO sessions (session_token, user_type, user_identifier, created_at, expires_at,
                                ip_address)
            VALUES (?, ?, ?, ?, ?, ?)
        ''', (session_token, user_type, user_identifier, now.isoformat(), expires.isoformat(), ip_address))
        conn.commit()

    return session_token
```

```
def validate_session(session_token: str) -> dict
```

Validate a session token and return user info if valid.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `session_token: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> dict`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```
def validate_session(session_token: str) -> dict:
    """Validate a session token and return user info if valid."""
    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute('''
            SELECT user_type, user_identifier, expires_at FROM sessions
            WHERE session_token = ?
        ''', (session_token,))
        row = cursor.fetchone()
```

```

if row:
    expires = datetime.fromisoformat(row['expires_at'])
    if datetime.now() < expires:
        return {
            'user_type': row['user_type'],
            'user_identifier': row['user_identifier']
        }
    else:
        # Session expired, delete it
        cursor.execute('DELETE FROM sessions WHERE session_token = ?', (session_token,))
        conn.commit()

return None

```

```
def delete_session(session_token: str)
```

Delete a session (logout).

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `session_token: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```

def delete_session(session_token: str):
    """Delete a session (logout)."""
    with get_connection() as conn:
        cursor = conn.cursor()
        cursor.execute('DELETE FROM sessions WHERE session_token = ?', (session_token,))
        conn.commit()

```

```
def cleanup_expired_sessions()
```

Delete all expired sessions.

Why these Python concepts were used

- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. **with** `get_connection()`: enters a context manager.

Code (copy-paste safe)

```

def cleanup_expired_sessions():
    """Delete all expired sessions."""
    with get_connection() as conn:
        cursor = conn.cursor()

```

```

cursor.execute(
    'DELETE FROM sessions WHERE expires_at < ?',
    (datetime.now().isoformat(),)
)
conn.commit()

```

```
def migrate_from_json(api_keys_file: str=None, data_file: str=None)
```

Migrate data from JSON files to SQLite database.

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `api_keys_file: str`, `data_file: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `base_dir = os.path.dirname(os.path.abspath(__file__))`.
2. **if** `api_keys_file` is `None`: branches conditionally.
3. **if** `data_file` is `None`: branches conditionally.
4. Assigns `migrated = {'api_keys': 0, 'clients': 0}`.
5. **if** `os.path.exists(api_keys_file)`: branches conditionally.
6. **if** `os.path.exists(data_file)`: branches conditionally.
7. **return** `migrated`.

Code (copy-paste safe)

```

def migrate_from_json(api_keys_file: str = None, data_file: str = None):
    """Migrate data from JSON files to SQLite database."""
    base_dir = os.path.dirname(os.path.abspath(__file__))

    if api_keys_file is None:
        api_keys_file = os.path.join(base_dir, 'api_keys.json')
    if data_file is None:
        data_file = os.path.join(base_dir, 'dashboard_data.json')

    migrated = {'api_keys': 0, 'clients': 0}

    # Migrate API keys (note: we can't migrate the actual keys, only the metadata)
    if os.path.exists(api_keys_file):
        try:
            with open(api_keys_file, 'r') as f:
                old_keys = json.load(f)

```

```

        print(f"Found {len(old_keys)} API keys to migrate")
        print("NOTE: Existing API keys cannot be migrated (they were stored in plain text)")
        print("You will need to generate new API keys for each trader")
        migrated['api_keys'] = len(old_keys)
    except Exception as e:
        print(f"Error reading API keys file: {e}")

# Migrate client data
if os.path.exists(data_file):
    try:
        with open(data_file, 'r') as f:
            data = json.load(f)

        clients_db = data.get('clients_db', {})
        for client_id, client_data in clients_db.items():
            save_client_data(client_id, client_data)
            migrated['clients'] += 1

        print(f"Migrated {migrated['clients']} clients")
    except Exception as e:
        print(f"Error migrating client data: {e}")

return migrated

```

Step 4.5 — Build dashboard/db.py

What to do. Create the file `dashboard/db.py` in your project root and paste in the code shown in this step. The file is **44** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

What this file is for. Lower-level convenience wrappers around the SQLAlchemy session for places that don't want the ORM overhead.

dashboard/db.py

44 loc · 0 classes · 1 functions · 4 imports

Lower-level convenience wrappers around the SQLAlchemy session for places that don't want the ORM overhead. It defines **1** module-level function, across **44** lines. Module docstring: *SQLAlchemy engine + session factory*.

Module docstring

SQLAlchemy engine + session factory.

Reads `DATABASE_URL` from environment (or `.env` file). Falls back to SQLite for legacy compatibility.

Set in `.env`: `DATABASE_URL=postgresql://postgres:password@localhost:5432/tradeopss`

Python concepts demonstrated in this module

- Exceptions
- f-strings
- Generators and yield

Imports — what each one is for

```
import os
```

Why imported. Operating-system interface. Path manipulation, environment variables, working-directory operations, exit codes, and thin wrappers around POSIX/Windows syscalls.

Used in this file. `os.environ`, `os.environ.get`, `os.path`, `os.path.abspath`, `os.path.dirname`, `os.path.join`

Example. `os.path.join(root, 'subdir', 'file.txt')` # joins with the OS-correct separator

Other common scenarios.

- `os.environ.get('API_KEY')` to read environment variables
- `os.makedirs(path, exist_ok=True)` to create nested directories
- `os.listdir(path)` to list a directory's contents
- `os.remove(path)` / `os.rename(src, dst)` to delete or move a file
- `os.getcwd()` / `os.chdir(path)` to inspect or change the working dir

```
from sqlalchemy import create_engine
```

Why imported. Python's most popular ORM and SQL toolkit. Models declare tables as classes; the engine handles connection pooling.

Used in this file. `create_engine`

Example. `session.query(User).filter_by(email=e).first()`

Other common scenarios.

- Column / relationship / ForeignKey declare schema
- `session.add(obj)`; `session.commit()`
- with `engine.begin()` as `conn`: `conn.execute(text('SQL'))`
- 2.0-style: `select(User).where(User.id == 1)`

```
from sqlalchemy.orm import sessionmaker
```

Why imported. Python's most popular ORM and SQL toolkit. Models declare tables as classes; the engine handles connection pooling.

Used in this file. `sessionmaker`

Example. `session.query(User).filter_by(email=e).first()`

Other common scenarios.

- Column / relationship / ForeignKey declare schema
- `session.add(obj)`; `session.commit()`
- with `engine.begin()` as `conn`: `conn.execute(text('SQL'))`

- 2.0-style: `select(User).where(User.id == 1)`

`from dotenv import load_dotenv`

Why imported. python-dotenv — load .env files into `os.environ` for twelve-factor configuration in development.

Used in this file. `load_dotenv`

Example. `load_dotenv()` # call once at process start

Other common scenarios.

- `dotenv_values('.env')` returns a dict without polluting `os.environ`
- Use a real secret store in production (vault, AWS SM, etc.)

Module constants

Each line below is followed by a plain-English note explaining what it does and why it is written that way.

```
DATABASE_URL = os.environ.get('DATABASE_URL',
    f"sqlite:///{"os.path.join(os.path.dirname(os.path.abspath(__file__)), 'dashboard.db')}")
```

Equivalent to `os.getenv`: reads `DATABASE_URL` from the environment, default `f"sqlite:///{"os.path.join(os.path.dirname(os.path.abspath(__file__)), 'dashboard.db')}"`.

Functions

```
def get_session()
```

Dependency-style session: use as context manager.

Why these Python concepts were used

- **generator (yield)** — The body uses **yield**, so calling it returns an iterator instead of a value. Items are produced lazily — the function only runs as far as the next **yield** on each iteration. Right choice when the caller iterates results and the dataset is large or open-ended.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **raise** — Raises an exception explicitly. Either signals an invalid argument the caller should fix, or re-raises after logging.

Step by step (top-level body)

1. Assigns `session = SessionLocal()`.
2. **try** block with 1 **except** clause, plus a **finally**.

Code (copy-paste safe)

```
def get_session():
    """Dependency-style session: use as context manager."""
    session = SessionLocal()
    try:
        yield session
        session.commit()
    except Exception:
```

```
        session.rollback()
        raise
    finally:
        session.close()
```

Step 4.6 — Build dashboard/models.py

What to do. Create the file `dashboard/models.py` in your project root and paste in the code shown in this step. The file is **330** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

What this file is for. SQLAlchemy ORM models. Each class corresponds to a table; fields use Column declarations; relationships are defined via `relationship()` and back-populated on the other side.

dashboard/models.py

330 loc · 18 classes · 0 functions · 3 imports

SQLAlchemy ORM models. Each class corresponds to a table; fields use Column declarations; relationships are defined via `relationship()` and back-populated on the other side. It defines **18** classes, across **330** lines. Module docstring: *SQLAlchemy ORM Models — mirrors the existing SQLite schema exactly*.

Module docstring

SQLAlchemy ORM Models — mirrors the existing SQLite schema exactly. Target: PostgreSQL (local dev first, then production).

Usage: `from dashboard.models import Base, ClientsData, UserCredentials, ... from dashboard.db import engine, SessionLocal`

Note: `server_default` is used everywhere so that raw SQL INSERTs (which bypass the ORM) still get correct column defaults.

Python concepts demonstrated in this module

- Classes and objects
- Inheritance

Imports — what each one is for

```
from datetime import datetime
```

Why imported. Dates, times, durations. The fundamental temporal types: `date`, `time`, `datetime`, `timedelta`, `timezone`.

Used in this file. *No direct attribute access detected — likely imported for side effects, re-export, or string references.*

Example. `datetime.now() - timedelta(days=7)` # one week ago

Other common scenarios.

- `datetime.strptime(s, '%Y-%m-%d')` parses a string
- `datetime.strftime(fmt)` formats one
- `datetime.fromtimestamp(n)` converts a Unix epoch
- `datetime.utcnow()` for UTC (better: `datetime.now(timezone.utc)`)

```
from sqlalchemy import BigInteger
from sqlalchemy import Column
from sqlalchemy import Float
from sqlalchemy import ForeignKey
from sqlalchemy import Index
from sqlalchemy import Integer
from sqlalchemy import SmallInteger
from sqlalchemy import String
from sqlalchemy import Text
from sqlalchemy import UniqueConstraint
from sqlalchemy import func
from sqlalchemy import text
```

Why imported. Python's most popular ORM and SQL toolkit. Models declare tables as classes; the engine handles connection pooling.

Used in this file. `Column`, `Float`, `ForeignKey`, `Index`, `Integer`, `SmallInteger`, `Text`, `UniqueConstraint`, `func`, `text`

Example. `session.query(User).filter_by(email=e).first()`

Other common scenarios.

- `Column` / `relationship` / `ForeignKey` declare schema
- `session.add(obj)`; `session.commit()`
- with `engine.begin()` as `conn`: `conn.execute(text('SQL'))`
- 2.0-style: `select(User).where(User.id == 1)`

```
from sqlalchemy.orm import DeclarativeBase
from sqlalchemy.orm import relationship
```

Why imported. Python's most popular ORM and SQL toolkit. Models declare tables as classes; the engine handles connection pooling.

Used in this file. `DeclarativeBase`, `relationship`

Example. `session.query(User).filter_by(email=e).first()`

Other common scenarios.

- `Column` / `relationship` / `ForeignKey` declare schema
- `session.add(obj)`; `session.commit()`
- with `engine.begin()` as `conn`: `conn.execute(text('SQL'))`
- 2.0-style: `select(User).where(User.id == 1)`

Classes

```
class Base(DeclarativeBase)
```

Code (copy-paste safe)

```
class Base(DeclarativeBase):
    pass

class ApiKey(Base)

    __tablename__ = 'api_keys'
    id = Column(Integer, primary_key=True, autoincrement=True)
    key_hash = Column(Text, unique=True, nullable=False)

Checkpoint — what works now. Your database schema exists. Run alembic upgrade head from the project root and the dashboard.db file should appear with all tables created. Open it with sqlite3 dashboard.db .schema to inspect the columns. You cannot yet write rows from application code — that comes in phase 9 — but the schema is in place.

Chapter 5 — Phase 3 — Talking to MetaTrader 5

The MT5 terminal exposes a Python API through the MetaTrader5 package. Before we can place a trade or read history, we need a thin wrapper that opens and closes the connection cleanly. That wrapper lives in `connectors/`; everything in later phases that talks to MT5 goes through it.

Files we build in this phase, in order:

- `connectors/mt5_connector.py`
- `connectors/mt5_automator.py`

Python concepts you'll meet in this phase

- Dunder methods (2) · f-strings (2) · Classes and objects (2) · Exceptions (2) · Comprehensions (1) · Lambdas (1) · Context managers (with-statements) (1)

Each is explained in Chapter 2 (the primer). The number in parentheses is how many of this phase's files use that concept.

Step 5.1 — Build `connectors/mt5_connector.py`

What to do. Create the file `connectors/mt5_connector.py` in your project root and paste in the code shown in this step. The file is **198** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

What this file is for. Manages the lifecycle of the MetaTrader 5 connection: initialize, login, shutdown, and reconnection on failure.

`connectors/mt5_connector.py`

198 loc · 1 classes · 0 functions · 2 imports

Manages the lifecycle of the MetaTrader 5 connection: initialize, login, shutdown, and reconnection on failure. It defines **1** class, across **198** lines.

Python concepts demonstrated in this module

- Classes and objects · Dunder methods · Exceptions · f-strings

Imports — what each one is for

```
import MetaTrader5 as mt5
```

Why imported. Official MetaQuotes Python API for MT5. Connects to a local terminal, places orders, reads tick/bar history.

Used in this file. `mt5.ORDER_FILLING_IOC`, `mt5.ORDER_TIME_GTC`, `mt5.ORDER_TYPE_BUY`, `mt5.ORDER_TYPE_SELL`, `mt5.TRADE_ACTION_DEAL`, `mt5.TRADE_RETCODE_DONE`, `mt5.account_info`, `mt5.history_deals_get`

Example. `mt5.initialize()`; `mt5.order_send(request)`

Other common scenarios.

- `mt5.symbols_get()` / `mt5.symbol_info(symbol)`
- `mt5.history_deals_get(from_, to_)` returns closed deals
- `mt5.account_info()` returns balance/equity/currency
- Always `mt5.shutdown()` in a finally to release the terminal

```
import pandas as pd
```

Why imported. DataFrame library — the workhorse for tabular data: loading CSV/Excel/SQL, joins, aggregations, time-series.

Used in this file. *No direct attribute access detected — likely imported for side effects, re-export, or string references.*

Example. `df = pd.read_csv(path)`; `df.groupby('symbol')['pnl'].sum()`

Other common scenarios.

- `df.merge(other, on='key')` joins like SQL
- `df.resample('1D').agg(...)` for time-series rebucketing
- `df.to_sql` / `df.to_excel` / `df.to_parquet` for output
- `df.loc[mask, 'col']` for label-based selection/assignment

Classes

```
class MT5Connector
```

Code (copy-paste safe)

```
class MT5Connector:
    def __init__(self, login, password, server, terminal_path=None):
        self.login = login
        self.password = password

```

Method: MT5Connector.__init__

```
def __init__(self, login, password, server, terminal_path=None)
```

Why these Python concepts were used

- **__init__** — The constructor. Runs after Python has allocated the instance; assigns starting attribute values to self.

Step by step (top-level body)

1. Assigns self.login = login.
2. Assigns self.password = password.
3. Assigns self.server = server.
4. Assigns self.terminal_path = terminal_path.
5. Assigns self.connected = False.

Code (copy-paste safe)

```
def __init__(self, login, password, server, terminal_path=None):
    self.login = login
    self.password = password
    self.server = server
    self.terminal_path = terminal_path
    self.connected = False
```

Method: MT5Connector.connect

```
def connect(self)
```

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns init_params = {}.
2. **if** self.terminal_path and 'exe' in self.terminal_path: branches conditionally.
3. **if** not mt5.initialize(**init_params): branches conditionally.
4. **if** not self.login or not self.password or (not self.server): branches conditionally.
5. Assigns authorized = mt5.login(self.login, password=self.password, server=self....
6. **if** authorized: branches conditionally (with an **else/elif** arm).
7. **return** self.connected.

Code (copy-paste safe)

```
def connect(self):
    init_params = {}
    if self.terminal_path and "exe" in self.terminal_path:
        init_params["path"] = self.terminal_path

    if not mt5.initialize(**init_params):
        print("initialize() failed, error code =", mt5.last_error())
        return False
```

```

    if not self.login or not self.password or not self.server:
        print("MT5 Credentials missing. Skipping login.")
        return False

    authorized = mt5.login(self.login, password=self.password, server=self.server)
    if authorized:
        self.connected = True
        print(f"Connected to MT5 account #{self.login}")
    else:
        print("failed to connect at account #{}, error code: {}".format(self.login, mt5.last_error()))

    return self.connected

```

Method: MT5Connector.shutdown

```
def shutdown(self)
```

Step by step (top-level body)

1. Calls `mt5.shutdown(...)` for its side effect.
2. Assigns `self.connected = False`.

Code (copy-paste safe)

```

def shutdown(self):
    mt5.shutdown()
    self.connected = False

```

Method: MT5Connector.get_deals

```
def get_deals(self, days=30, from_date=None)
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `init_params = {}`.
2. **if** `self.terminal_path` and `'exe'` in `self.terminal_path`: branches conditionally.
3. **if** `not mt5.initialize(**init_params)`: branches conditionally.
4. **if** `self.login` and `self.password` and `self.server`: branches conditionally.
5. Imports `time` (lazy import inside the function).
6. Assigns `to_timestamp = time.time() + 86400`.
7. **if** `from_date`: branches conditionally (with an **else/elif** arm).
8. **try** block with 1 **except** clause.
9. **if** `deals` is `None`: branches conditionally.

10. return deals.

Code (copy-paste safe)

```
def get_deals(self, days=30, from_date=None):
    # Ensure MT5 is initialized and logged in for the current thread
    init_params = {}
    if self.terminal_path and "exe" in self.terminal_path:
        init_params["path"] = self.terminal_path

    if not mt5.initialize(**init_params):
        print(f"get_deals: mt5.initialize() failed with path: {self.terminal_path}")
        print("Error code:", mt5.last_error())
        return []

    if self.login and self.password and self.server:
        # Ensure login is int
        try:
            login_int = int(self.login)
        except:
            print(f"Invalid login format: {self.login}")
            return []

        if not mt5.login(login_int, password=self.password, server=self.server):
            print(f"get_deals: mt5.login failed for {self.login}")
            print("Error code:", mt5.last_error())
            return []

    import time
    to_timestamp = time.time() + 86400 # Add buffer (1 day)

    if from_date:
        from_timestamp = from_date.timestamp()
    elif days is None:
        from_timestamp = 0.0
    else:
        # Calculate from_timestamp relative to NOW, not the buffered to_timestamp
        from_timestamp = time.time() - (days * 24 * 3600)

    try:
        # Use timestamps to avoid datetime issues
        deals = mt5.history_deals_get(from_timestamp, to_timestamp)
    except Exception as e:
        print(f"get_deals: Exception calling history_deals_get: {e}")
        return []

    if deals is None:
        print("No deals found. Error code={}".format(mt5.last_error()))
        return []

    return deals
```

Method: MT5Connector.get_deals_by_position

```
def get_deals_by_position(self, position_id)
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't

have to handle it.

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **if** not self.connected: branches conditionally.
2. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def get_deals_by_position(self, position_id):
    if not self.connected: return []
    try:
        deals = mt5.history_deals_get(position=position_id)
        if deals is None:
            return []
        return deals
    except Exception as e:
        print(f"get_deals_by_position error: {e}")
        return []
```

Method: MT5Connector.get_account_info

```
def get_account_info(self)
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **if** not self.connected: branches conditionally.
2. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def get_account_info(self):
    if not self.connected: return None
    try:
        return mt5.account_info()
    except Exception as e:
        print(f"get_account_info error: {e}")
        return None
```

Method: MT5Connector.get_positions

```
def get_positions(self)
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **if** not self.connected: branches conditionally.
2. **try** block with 2 **except** clauses.

Code (copy-paste safe)

```
def get_positions(self):
    if not self.connected: return []
    try:
        positions = mt5.positions_get()
        if positions is None:
            return []
        return positions
    except Exception as e:
        print(f"get_positions error: {e}")
        return []
    except Exception as e:
        print(f"get_account_info error: {e}")
        return None
```

Method: MT5Connector.get_positions

```
def get_positions(self)
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **if** not self.connected: branches conditionally.
2. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def get_positions(self):
    if not self.connected: return []
    try:
        positions = mt5.positions_get()
        if positions is None:
            return []
        return positions
    except Exception as e:
        print(f"get_positions error: {e}")
        return []
```

Method: MT5Connector.place_order

```
def place_order(self, symbol, order_type, volume, sl_points=None, tp_points=None, comment=''):
```

Places a market order. order_type: 'BUY' or 'SELL' sl_points: Stop Loss in points (optional) tp_points: Take Profit in points (optional)

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **if** not self.connected: branches conditionally.
2. **if** not mt5.symbol_select(symbol, True): branches conditionally.
3. Assigns symbol_info = mt5.symbol_info(symbol).
4. **if** symbol_info is None: branches conditionally.
5. **if** order_type.upper() == 'BUY': branches conditionally (with an **else/elif** arm).
6. Assigns request = {'action': mt5.TRADE_ACTION_DEAL, 'symbol': symbol, 'volu....
7. Assigns point = symbol_info.point.
8. **if** sl_points: branches conditionally.
9. **if** tp_points: branches conditionally.
10. Assigns result = mt5.order_send(request).
11. **if** result.retcode != mt5.TRADE_RETCODE_DONE: branches conditionally.
12. Calls print(...) for its side effect.
13. **return** True.

Code (copy-paste safe)

```
def place_order(self, symbol, order_type, volume, sl_points=None, tp_points=None, comment=""):
    """
    Places a market order.
    order_type: 'BUY' or 'SELL'
    sl_points: Stop Loss in points (optional)
    tp_points: Take Profit in points (optional)
    """
    if not self.connected:
        if not self.connect():
            return False

    # Ensure symbol is selected
    if not mt5.symbol_select(symbol, True):
        print(f"Failed to select symbol {symbol}")
        return False

    symbol_info = mt5.symbol_info(symbol)
    if symbol_info is None:
        print(f"{symbol} not found")
        return False
```

```

# Determine order type and price
if order_type.upper() == 'BUY':
    mt5_type = mt5.ORDER_TYPE_BUY
    price = mt5.symbol_info_tick(symbol).ask
elif order_type.upper() == 'SELL':
    mt5_type = mt5.ORDER_TYPE_SELL
    price = mt5.symbol_info_tick(symbol).bid
else:
    print(f"Invalid order type: {order_type}")
    return False

request = {
    "action": mt5.TRADE_ACTION_DEAL,
    "symbol": symbol,
    "volume": float(volume),
    "type": mt5_type,
    "price": price,
    "deviation": 20,
    "magic": 234000,
    "comment": comment,
    "type_time": mt5.ORDER_TIME_GTC,
    "type_filling": mt5.ORDER_FILLING_IOC,
}

# Calculate SL/TP prices if points provided
point = symbol_info.point
if sl_points:
    if mt5_type == mt5.ORDER_TYPE_BUY:
        request["sl"] = price - (sl_points * point)
    else:
        request["sl"] = price + (sl_points * point)

if tp_points:
    if mt5_type == mt5.ORDER_TYPE_BUY:
        request["tp"] = price + (tp_points * point)
    else:
        request["tp"] = price - (tp_points * point)

# Send order
result = mt5.order_send(request)

if result.retcode != mt5.TRADE_RETCODE_DONE:
    print(f"Order failed: {result.comment} ({result.retcode})")
    return False

print(f"Order placed successfully: {result.order}")
return True

```

Step 5.2 — Build connectors/mt5_automator.py

What to do. Create the file `connectors/mt5_automator.py` in your project root and paste in the code shown in this step. The file is **2228** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

What this file is for. Higher-level helper for issuing MT5 commands without callers having to handle the request/result tuples directly.

connectors/mt5_automator.py

2228 loc · 1 classes · 2 functions · 12 imports

Higher-level helper for issuing MT5 commands without callers having to handle the request/result tuples directly. It defines **1** class and **2** module-level functions, across **2,228** lines.

Python concepts demonstrated in this module

- Classes and objects
- Comprehensions
- Context managers (with-statements)
- Dunder methods
- Exceptions
- f-strings
- Lambdas

Imports — what each one is for

```
import sys
```

Why imported. Access to the running interpreter — `argv`, `stdin/stdout`, exit codes, the import search path, and the platform name.

Used in this file. `sys._MEIPASS`

Example. `sys.exit(1)` # terminate the process with a non-zero status

Other common scenarios.

- `sys.argv[1:]` reads the command-line arguments
- `sys.path.insert(0, 'extra')` prepends to the import search path
- `sys.stderr.write(msg)` writes to standard error
- `sys.platform` tells you 'win32', 'linux', or 'darwin'
- `sys.modules` is the global cache of already-imported modules

```
import os
```

Why imported. Operating-system interface. Path manipulation, environment variables, working-directory operations, exit codes, and thin wrappers around POSIX/Windows syscalls.

Used in this file. `os.add_dll_directory`, `os.environ`, `os.environ.get`, `os.getenv`, `os.path`, `os.path.abspath`, `os.path.basename`, `os.path.dirname`

Example. `os.path.join(root, 'subdir', 'file.txt')` # joins with the OS-correct separator

Other common scenarios.

- `os.environ.get('API_KEY')` to read environment variables
- `os.makedirs(path, exist_ok=True)` to create nested directories
- `os.listdir(path)` to list a directory's contents
- `os.remove(path)` / `os.rename(src, dst)` to delete or move a file
- `os.getcwd()` / `os.chdir(path)` to inspect or change the working dir

`import winreg`

Why imported. Read and write the Windows registry — used to discover installed MetaTrader terminals.

Used in this file. `winreg.EnumKey`, `winreg.HKEY_CURRENT_USER`, `winreg.HKEY_LOCAL_MACHINE`, `winreg.OpenKey`, `winreg.QueryValueEx`

Example. `winreg.OpenKey(HKEY_LOCAL_MACHINE, r'Software\X')`

Other common scenarios.

- `QueryValueEx` returns a (value, type) tuple
- `EnumKey` / `EnumValue` iterate sub-keys

`from pathlib import Path`

Why imported. Object-oriented filesystem paths. Replaces most uses of `os.path` with chainable methods and operator overloading.

Used in this file. *No direct attribute access detected — likely imported for side effects, re-export, or string references.*

Example. `Path('logs') / f'{name}.log' # /` is overloaded to join

Other common scenarios.

- `p.exists()`, `p.is_file()`, `p.is_dir()` for predicates
- `p.read_text()` / `p.write_text(content)` for one-shot file I/O
- `p.glob('**/*.py')` to walk a tree with a pattern
- `p.with_suffix('.bak')` to derive a sibling path

`from dotenv import load_dotenv`

Why imported. `python-dotenv` — load `.env` files into `os.environ` for twelve-factor configuration in development.

Used in this file. `load_dotenv`

Example. `load_dotenv()` # call once at process start

Other common scenarios.

- `dotenv_values('.env')` returns a dict without polluting `os.environ`
- Use a real secret store in production (vault, AWS SM, etc.)

`import logging`

Why imported. Structured, levelled logging. Replaces print() with filterable, formattable output that can route to files, stderr, syslog, or HTTP endpoints.

Used in this file. logging.INFO, logging.basicConfig, logging.debug, logging.error, logging.exception, logging.info, logging.warning

Example. logging.getLogger(__name__).info('connected to %s', host)

Other common scenarios.

- .debug() / .info() / .warning() / .error() / .exception()
- logger.exception() captures the current traceback automatically
- logging.basicConfig(level=logging.INFO) for quick setup
- Handlers and Formatters route logs to files / streams / syslog

import subprocess

Why imported. Run external programs. The standard way to spawn a child process, capture its output, and wait for its exit code.

Used in this file. subprocess.run

Example. subprocess.run(['git', 'rev-parse', 'HEAD'], capture_output=True, text=True, check=True)

Other common scenarios.

- Popen(...) for streaming I/O while the process is alive
- check_output(cmd) returns stdout as text and raises on failure
- DEVNULL / PIPE redirect stdin/stdout/stderr
- shell=True interprets the string with the system shell (security risk)

import psutil

Why imported. Cross-platform process and system information — find a running terminal, check CPU/memory, kill a stale process.

Used in this file. psutil.AccessDenied, psutil.NoSuchProcess, psutil.ZombieProcess, psutil.disk_partitions, psutil.process_iter

Example. psutil.process_iter(['name']) # iterate live processes

Other common scenarios.

- psutil.Process(pid).terminate() / .kill()
- psutil.cpu_percent(interval=1.0) measures CPU usage
- psutil.virtual_memory() returns RAM stats

import time

Why imported. Timestamps and sleep. Lower-level than datetime — works in Unix-epoch seconds.

Used in this file. time.sleep, time.time

Example. time.sleep(1.5) # pause this thread for 1.5 seconds

Other common scenarios.

- `time.time()` returns seconds since the epoch
- `time.monotonic()` for measuring elapsed time (never goes backward)
- `time.perf_counter()` for high-precision benchmarking
- `time.strftime` / `time.strptime` mirror the `datetime` versions

```
from time import sleep
```

Why imported. Timestamps and `sleep`. Lower-level than `datetime` — works in Unix-epoch seconds.

Used in this file. `sleep`

Example. `time.sleep(1.5)` # pause this thread for 1.5 seconds

Other common scenarios.

- `time.time()` returns seconds since the epoch
- `time.monotonic()` for measuring elapsed time (never goes backward)
- `time.perf_counter()` for high-precision benchmarking
- `time.strftime` / `time.strptime` mirror the `datetime` versions

```
import ctypes
```

Why imported. Call C functions from shared libraries (DLLs / `.so` / `.dylib`). Used here to reach Win32 APIs the `stdlib` doesn't expose.

Used in this file. *No direct attribute access detected — likely imported for side effects, re-export, or string references.*

Example. `ctypes.windll.user32.MessageBoxW(0, 'hi', 't', 0)`

Other common scenarios.

- `CDLL('libfoo.so')` loads a Unix shared object
- Define `argtypes`/`restype` to get type-checked calls
- `c_int` / `c_char_p` / Structure mirror C type layouts

```
from ctypes import wintypes
```

Why imported. Call C functions from shared libraries (DLLs / `.so` / `.dylib`). Used here to reach Win32 APIs the `stdlib` doesn't expose.

Used in this file. *No direct attribute access detected — likely imported for side effects, re-export, or string references.*

Example. `ctypes.windll.user32.MessageBoxW(0, 'hi', 't', 0)`

Other common scenarios.

- `CDLL('libfoo.so')` loads a Unix shared object
- Define `argtypes`/`restype` to get type-checked calls
- `c_int` / `c_char_p` / Structure mirror C type layouts

Classes

```

class MT5Automator
    _symbol_cache = {}
    _symbol_cache_timestamp = {}
    _cache_ttl = 300

```

Code (copy-paste safe)

```

class MT5Automator:

```

Method: MT5Automator.__init__

```
def __init__(self, login, password, server, symbol=None, terminal_path=None)
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.
- **__init__** — The constructor. Runs after Python has allocated the instance; assigns starting attribute values to self.

Step by step (top-level body)

1. **try** block with 1 **except** clause.
2. Assigns `self.password = str(password) if password else "`.
3. Assigns `self.server = str(server) if server else "`.
4. Assigns `self.symbol = symbol`.
5. Assigns `self.terminal_path = terminal_path`.

6. Assigns `self.sl_points = float(os.getenv('MT5_SL_POINTS') or os.getenv('MT5_STOPLO....`
7. Assigns `self.tp_points = float(os.getenv('MT5_TP_POINTS') or os.getenv('MT5_TAKEPR....`
8. Assigns `self.default_volume = float(os.getenv('MT5_VOLUME', '1'))`.
9. Assigns `self.rollover_executed_today = {}`.
10. Assigns `self.connected_symbol = None`.
11. Assigns `self.is_plexy_server = 'plexy' in server.lower()` if server else False.
12. **if** `self.is_plexy_server`: branches conditionally.
13. Assigns `self.connected = False`.
14. Assigns `self.last_error = None`.

Code (copy-paste safe)

```
def __init__(self, login, password, server, symbol=None, terminal_path=None):
    # Safely convert login to integer
    try:
        self.login = int(str(login).strip()) if login else 0
    except (ValueError, TypeError):
        logging.error(f'Invalid login format: {login}')
        self.login = 0

    self.password = str(password) if password else ""

```

Method: MT5Automator._get_cached_terminal_path

```
def _get_cached_terminal_path(self)
    Get previously successful terminal path for faster connection
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Imports tempfile (lazy import inside the function).
2. Assigns `cache_file = os.path.join(tempfile.gettempdir(), 'mt5_terminal_cache.t....`
3. **try** block with 1 **except** clause.
4. **return** None.

Code (copy-paste safe)

```
def _get_cached_terminal_path(self):
    """Get previously successful terminal path for faster connection"""
    import tempfile

        return False

```

Method: MT5Automator.ensure_session_integrity

```
def ensure_session_integrity(self)
```

Ensure MT5 session is properly initialized and maintained Call this at application startup and periodically during operation

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

def ensure_session_integrity(self):
    """
    Ensure MT5 session is properly initialized and maintained
    Call this at application startup and periodically during operation
    """
    try:
        logging.info("[SETUP] Ensuring MT5 session integrity...")

        # Check if MT5 is initialized
        if not mt5.initialize():
            logging.warning("MT5 not initialized, attempting to initialize...")
            if not mt5.initialize():
                logging.error("[ERROR] Failed to initialize MT5")
                return False

        # Check if we're logged in
        if not mt5.terminal_info():
            logging.warning("MT5 terminal info not available, attempting connection...")
            if not self.connect():
                logging.error("[ERROR] Failed to connect to MT5")
                return False

```

```

```

Method: MT5Automator._log_available_symbols

```
def _log_available_symbols(self, failed_symbol)
```

Log some available symbols for debugging

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with `append`, and clearer about intent: this is a transform, not a side-effecting loop.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to `sum`, `any`, `all`, or `max` where the intermediate list would be wasted.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def _log_available_symbols(self, failed_symbol):
    """Log some available symbols for debugging"""
    try:
        # Get all available symbols

return sl_price, tp_price

```

Method: MT5Automator.place_order

```
def place_order(self, symbol, order_type, volume=None, sl=None, tp=None, comment=None)
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression ([f(x) for x in xs]). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **raise** — Raises an exception explicitly. Either signals an invalid argument the caller should fix, or re-raises after logging.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. try block with 1 **except** clause.

Code (copy-paste safe)

```

Method: MT5Automator.is_connected

```
def is_connected(self)
```

Check if MT5 connection is still active

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def is_connected(self):
    """Check if MT5 connection is still active"""
    try:
        # Try to get account info to test connection
        account_info = mt5.account_info()

        return False
```

Method: MT5Automator.check_connection_and_disconnect_if_needed

```
def check_connection_and_disconnect_if_needed(self)
```

Check connection and disconnect if lost

Step by step (top-level body)

1. `if not self.is_connected()`: branches conditionally.
2. `return True`.

Code (copy-paste safe)

```
def check_connection_and_disconnect_if_needed(self):
    """Check connection and disconnect if lost"""
    if not self.is_connected():
        logging.warning("MT5 connection lost, disconnecting...")
        self.disconnect()
        return False
    return True
```

Method: MT5Automator.disconnect

```
def disconnect(self)
```

Properly disconnect from MT5 with enhanced cleanup and terminal closure

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def disconnect(self):
    """Properly disconnect from MT5 with enhanced cleanup and terminal closure"""
    try:
        # First, perform standard MT5 API shutdown

        return 0
```

Method: MT5Automator.close_trade

```
def close_trade(self, ticket, retries=3, delay=2)
```

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **for** attempt in range(retries): iterates.
2. Calls logging.error(...) for its side effect.
3. **return** not self.is_trade_open(ticket).

Code (copy-paste safe)

```
def close_trade(self, ticket, retries=3, delay=2):
    for attempt in range(retries):
        positions = mt5.positions_get(ticket=ticket)
        if not positions:
            logging.info(f"Trade {ticket} already closed.")
            return True
```

```

Method: MT5Automator.extract_tradovate_account_from_comment

```
def extract_tradovate_account_from_comment(self, comment)
```

Extract Tradovate account number from MT5 comment Args: comment: MT5 order comment (e.g., "MFFUEVSTP326057008") Returns: str: Tradovate account number or "Unknown" if not found

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def extract_tradovate_account_from_comment(self, comment):
    """Extract Tradovate account number from MT5 comment

```

```
return False
```

```
def get_installed_mt5_terminals()
```

Detect installed MetaTrader 5 terminals on Windows Returns a list of dictionaries with terminal info

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to `sum`, `any`, `all`, or `max` where the intermediate list would be wasted.
- **lambda** — Uses a single-expression anonymous function — typically as the `key=` for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns `terminals = []`.
2. Calls `logging.info(...)` for its side effect.
3. Assigns `username = os.getenv('USERNAME', '')`.
4. Assigns `common_paths = ['C:\\Program Files\\MetaTrader 5', 'C:\\Program Files (x...`
5. Assigns `registry_paths = [(winreg.HKEY_LOCAL_MACHINE, 'SOFTWARE\\MetaQuotes\\Termi...`
6. **for** `(hkey, reg_path) in registry_paths`: iterates.
7. **for** `path in common_paths`: iterates.
8. **try** block with 1 **except** clause.
9. Assigns `current_dir = os.path.dirname(os.path.abspath(__file__))`.
10. Assigns `parent_dir = os.path.dirname(current_dir)`.
11. Assigns `portable_paths = [os.path.join(parent_dir, 'MT5'), os.path.join(parent_dir...`
12. **for** `path in portable_paths`: iterates.
13. **try** block with 1 **except** clause.
14. Assigns `unique_terminals = []`.
15. ... and 13 more statement(s) in the body.

Code (copy-paste safe)

```

return final_terminals

```

Checkpoint — what works now. You can connect to the MT5 terminal from Python. Open the terminal, log in, then in a REPL: from connectors.mt5_connector import MT5Connector; MT5Connector().connect(). A successful return means the rest of the trading engine has something to talk to.

Chapter 6 — Phase 4 — Indicators and strategies

A strategy is a recipe that decides when to buy or sell. Most strategies are built out of *technical indicators* — RSI, moving averages, Bollinger Bands. Each indicator is a tiny pure function: it takes a pandas DataFrame of OHLC bars and returns a Series of values. We build the helper module first, then a single indicator template, then the rest, and finally the strategy that combines them.

Files we build in this phase, in order:

- trader_companion/signals/__init__.py
- trader_companion/signals/sma.py
- trader_companion/signals/ema.py
- trader_companion/signals/rsi.py
- trader_companion/signals/macd.py
- trader_companion/signals/bb.py
- trader_companion/signals/atr.py
- trader_companion/signals/adx.py
- trader_companion/signals/dmi.py
- trader_companion/signals/cci.py
- trader_companion/signals/momentum.py
- trader_companion/signals/roc.py
- trader_companion/signals/obv.py
- trader_companion/signals/mfi.py
- trader_companion/signals/stochastic.py
- trader_companion/signals/supertrend.py
- trader_companion/signals/sar.py
- trader_companion/signals/tsi.py
- trader_companion/signals/wr.py
- trader_companion/signals/cmo.py
- trader_companion/signals/coppock_curve.py
- trader_companion/signals/donchian_channel.py
- trader_companion/signals/elder_ray.py
- trader_companion/signals/fractal.py
- trader_companion/signals/gator_oscillator.py
- trader_companion/signals/keltner_channel.py

- `trader_companion/signals/price_channel.py`
- `trader_companion/signals/ultimate_oscillator.py`
- `trader_companion/signals/vortex.py`
- `trader_companion/strategies/__init__.py`
- `trader_companion/strategies/rsi_overbought_oversold.py`

Python concepts you'll meet in this phase

- Comprehensions (18) · Exceptions (18) · Type hints (11) · f-strings (1)

Each is explained in Chapter 2 (the primer). The number in parentheses is how many of this phase's files use that concept.

Step 6.1 — Build `trader_companion/signals/__init__.py`

What to do. Create the file `trader_companion/signals/__init__.py` in your project root and paste in the code shown in this step. The file is **2** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

`trader_companion/signals/__init__.py`

2 loc · 0 classes · 0 functions · 0 imports

About the signals folder

Each file in `trader_companion/signals/` implements a single technical indicator. They follow the same shape: a function that takes a pandas DataFrame of OHLC bars and returns a Series of the indicator's values. Many are placeholders today — the signals that are wired into strategies are **rsi**, **ema**, **sma**, **macd**, **bb**, **atr**, and **supertrend**.

Package marker. Importing this folder as a module runs the code here (often empty, sometimes used to re-export public names). across **2** lines.

Step 6.2 — Build `trader_companion/signals/sma.py`

What to do. Create the file `trader_companion/signals/sma.py` in your project root and paste in the code shown in this step. The file is **27** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

trader_companion/signals/sma.py

27 loc · 0 classes · 1 functions · 3 imports

Single-indicator module — see the signals folder note above. Most of the work is a pandas computation feeding off OHLC bars. It defines **1** module-level function, across **27** lines.

Python concepts demonstrated in this module

- Comprehensions
- Exceptions

Imports — what each one is for

```
import MetaTrader5 as mt5
```

Why imported. Official MetaQuotes Python API for MT5. Connects to a local terminal, places orders, reads tick/bar history.

Used in this file. `mt5.copy_rates_from_pos`

Example. `mt5.initialize(); mt5.order_send(request)`

Other common scenarios.

- `mt5.symbols_get()` / `mt5.symbol_info(symbol)`
- `mt5.history_deals_get(from_, to_)` returns closed deals
- `mt5.account_info()` returns balance/equity/currency
- Always `mt5.shutdown()` in a finally to release the terminal

```
import pandas as pd
```

Why imported. DataFrame library — the workhorse for tabular data: loading CSV/Excel/SQL, joins, aggregations, time-series.

Used in this file. `pd.Series`

Example. `df = pd.read_csv(path); df.groupby('symbol')['pnl'].sum()`

Other common scenarios.

- `df.merge(other, on='key')` joins like SQL
- `df.resample('1D').agg(...)` for time-series rebucketing
- `df.to_sql` / `df.to_excel` / `df.to_parquet` for output
- `df.loc[mask, 'col']` for label-based selection/assignment

```
import numpy as np
```

Why imported. N-dimensional arrays — vectorised numerical computation. Backs pandas; used directly for indicator math.

Used in this file. `np.array`

Example. `np.where(close > open, 1, -1)` # vectorised conditional

Other common scenarios.

- Broadcasting: `arr * scalar`, `arr + arr2` work element-wise
- `np.nan / np.isnan(x)` for missing values
- `np.array(list)` creates a typed array; choose dtype carefully

Functions

```
def get_sma_signal(symbol, timeframe, period=21, return_value=False)
```

Get SMA value for a given symbol and timeframe. Args: symbol: Trading symbol timeframe: MT5 timeframe period: SMA period return_value: If True, returns the SMA value Returns: SMA value or None

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with `append`, and clearer about intent: this is a transform, not a side-effecting loop.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def get_sma_signal(symbol, timeframe, period=21, return_value=False):
    """
    Get SMA value for a given symbol and timeframe.
    Args:
        symbol: Trading symbol
        timeframe: MT5 timeframe
        period: SMA period
        return_value: If True, returns the SMA value
    Returns:
        SMA value or None
    """
    try:
        rates = mt5.copy_rates_from_pos(symbol, timeframe, 0, period + 10)
        if rates is None or len(rates) < period:
            return None
        closes = np.array([rate[4] for rate in rates])
        sma = pd.Series(closes).rolling(window=period).mean().iloc[-1]
        if return_value:
            return sma
        return sma
    except Exception:
        return None
```

Step 6.3 — Build `trader_companion/signals/ema.py`

What to do. Create the file `trader_companion/signals/ema.py` in your project root and paste in the code shown in this step. The file is **27** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

trader_companion/signals/ema.py

27 loc · 0 classes · 1 functions · 3 imports

Single-indicator module — see the signals folder note above. Most of the work is a pandas computation feeding off OHLC bars. It defines **1** module-level function, across **27** lines.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def get_ema_signal(symbol, timeframe, period=21, return_value=False):
    """
    Get EMA value for a given symbol and timeframe.
    Args:
        symbol: Trading symbol
        timeframe: MT5 timeframe
        period: EMA period
        return_value: If True, returns the EMA value
    Returns:
        EMA value or None
    """
    try:
        rates = mt5.copy_rates_from_pos(symbol, timeframe, 0, period + 10)
        if rates is None or len(rates) < period:
            return None
        closes = np.array([rate[4] for rate in rates])
        ema = pd.Series(closes).ewm(span=period, adjust=False).mean().iloc[-1]
        if return_value:
            return ema
        return ema
    except Exception:
        return None
```

Step 6.4 — Build trader_companion/signals/rsi.py

What to do. Create the file `trader_companion/signals/rsi.py` in your project root and paste in the code shown in this step. The file is **150** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

What this file is for. Relative Strength Index. The most-developed signal in the tree — illustrates how the rest of the signals are organised.

trader_companion/signals/rsi.py

150 loc · 0 classes · 4 functions · 4 imports

Relative Strength Index. The most-developed signal in the tree — illustrates how the rest of the signals are organised. It defines **4** module-level functions, across **150** lines. Module docstring: *RSI Signal Generator*

Module docstring

RSI Signal Generator Provides RSI-based trading signals for automated trading

Imports — what each one is for

```
import logging
```

Why imported. Structured, levelled logging. Replaces `print()` with filterable, formattable output that can route to files, stderr, syslog, or HTTP endpoints.

Used in this file. `logging.debug`, `logging.error`, `logging.warning`

Example. `logging.getLogger(__name__).info('connected to %s', host)`

Other common scenarios.

- `.debug()` / `.info()` / `.warning()` / `.error()` / `.exception()`
- `logger.exception()` captures the current traceback automatically
- `logging.basicConfig(level=logging.INFO)` for quick setup
- Handlers and Formatters route logs to files / streams / syslog

```
import MetaTrader5 as mt5
```

Why imported. Official MetaQuotes Python API for MT5. Connects to a local terminal, places orders, reads tick/bar history.

Used in this file. `mt5.TIMEFRAME_M5`, `mt5.copy_rates_from_pos`

Example. `mt5.initialize(); mt5.order_send(request)`

Other common scenarios.

- `mt5.symbols_get()` / `mt5.symbol_info(symbol)`
- `mt5.history_deals_get(from_, to_)` returns closed deals
- `mt5.account_info()` returns balance/equity/currency
- Always `mt5.shutdown()` in a finally to release the terminal

```
import numpy as np
```

Why imported. N-dimensional arrays — vectorised numerical computation. Backs pandas; used directly for indicator math.

Used in this file. *No direct attribute access detected — likely imported for side effects, re-export, or string references.*

Example. `np.where(close > open, 1, -1)` # vectorised conditional

Other common scenarios.

- Broadcasting: `arr * scalar`, `arr + arr2` work element-wise
- `np.nan` / `np.isnan(x)` for missing values
- `np.array(list)` creates a typed array; choose dtype carefully

```
from typing import Union
from typing import Tuple
from typing import Optional
```

Why imported. Type-hint primitives — generics, unions, Optional, Callable, Protocol, TypeVar, TypedDict.

Used in this file. Optional, Tuple, Union

Example. `def lookup(k: str) -> Optional[int]: ...`

Other common scenarios.

- `List[int]` / `Dict[str, Any]` / `Tuple[int, str]` (or bare `list[int]`+ on 3.9+)
- `Callable[[int, int], int]` for function signatures
- Protocol for structural typing (duck typing with checks)
- `TypeVar('T')` for generic functions and classes

Functions

```
def calculate_rsi(prices: list, period: int=14) -> float
```

Calculate RSI (Relative Strength Index) Args: prices: List of closing prices period: RSI calculation period Returns: RSI value (0-100)

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `prices: list, period: int`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> float`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with `append`, and clearer about intent: this is a transform, not a side-effecting loop.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **if** `len(prices) < period + 1`: branches conditionally.
2. Assigns `deltas = [prices[i] - prices[i - 1] for i in range(1, len(prices))]`.
3. Assigns `gains = [max(0, delta) for delta in deltas]`.
4. Assigns `losses = [max(0, -delta) for delta in deltas]`.
5. **if** `len(gains) >= period`: branches conditionally (with an **else/elif** arm).
6. **if** `avg_loss == 0`: branches conditionally.
7. Assigns `rs = avg_gain / avg_loss`.
8. Assigns `rsi = 100 - 100 / (1 + rs)`.
9. **return** `rsi`.

Code (copy-paste safe)

```
def calculate_rsi(prices: list, period: int = 14) -> float:
    """
    Calculate RSI (Relative Strength Index)

    Args:
        prices: List of closing prices
        period: RSI calculation period

    Returns:
        RSI value (0-100)
    """
    if len(prices) < period + 1:
        return 50.0 # Neutral RSI if not enough data

    # Calculate price changes
    deltas = [prices[i] - prices[i-1] for i in range(1, len(prices))]

    # Separate gains and losses
    gains = [max(0, delta) for delta in deltas]
    losses = [max(0, -delta) for delta in deltas]

    # Calculate average gains and losses
    if len(gains) >= period:
        avg_gain = sum(gains[-period:]) / period
        avg_loss = sum(losses[-period:]) / period
    else:
        avg_gain = sum(gains) / len(gains) if gains else 0
        avg_loss = sum(losses) / len(losses) if losses else 0

    rs = avg_gain / avg_loss
    rsi = 100 - 100 / (1 + rs)
    return rsi
```

```

    avg_loss = sum(losses) / len(losses) if losses else 0

    # Calculate RSI
    if avg_loss == 0:
        return 100.0

    rs = avg_gain / avg_loss
    rsi = 100 - (100 / (1 + rs))

    return rsi

```

```
def get_price_data(symbol: str, timeframe: int, count: int=100) -> Optional[list]
```

Get price data from MT5 Args: symbol: Trading symbol timeframe: MT5 timeframe constant count: Number of bars to retrieve Returns: List of closing prices or None if error

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., symbol: str, timeframe: int, count: int). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type -> Optional[list]. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression ([f(x) for x in xs]). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

def get_price_data(symbol: str, timeframe: int, count: int = 100) -> Optional[list]:
    """
    Get price data from MT5

    Args:
        symbol: Trading symbol
        timeframe: MT5 timeframe constant
        count: Number of bars to retrieve

    Returns:
        List of closing prices or None if error
    """
    try:
        # Get rates from MT5
        rates = mt5.copy_rates_from_pos(symbol, timeframe, 0, count)

        if rates is None or len(rates) == 0:
            logging.warning(f"No price data available for {symbol}")

```

```

        return None

    # Extract closing prices
    closes = [rate[4] for rate in rates] # rate[4] is close price

    return closes

except Exception as e:
    logging.error(f"Error getting price data for {symbol}: {e}")
    return None

def get_rsi_signal(symbol: str, timeframe: int=mt5.TIMEFRAME_M5, period: int=14, overbought: float=70,
    oversold: float=30, return_value: bool=False) -> Union[str, Tuple[str, float]]

```

Get RSI trading signal Args: symbol: Trading symbol timeframe: MT5 timeframe constant period: RSI calculation period overbought: Overbought threshold oversold: Oversold threshold return_value: Whether to return RSI value along with signal Returns: Trading signal ('buy', 'sell', 'hold') or tuple of (signal, rsi_value)

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., symbol: str, timeframe: int, period: int). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type -> Union[str, Tuple[str, float]]. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. try block with 1 **except** clause.

Code (copy-paste safe)

```

def get_rsi_signal(symbol: str, timeframe: int = mt5.TIMEFRAME_M5,
    period: int = 14, overbought: float = 70, oversold: float = 30,
    return_value: bool = False) -> Union[str, Tuple[str, float]]:
    """
    Get RSI trading signal

    Args:
        symbol: Trading symbol
        timeframe: MT5 timeframe constant
        period: RSI calculation period
        overbought: Overbought threshold
        oversold: Oversold threshold
        return_value: Whether to return RSI value along with signal

    Returns:
        Trading signal ('buy', 'sell', 'hold') or tuple of (signal, rsi_value)
    """
    try:

```

```

# Get price data
prices = get_price_data(symbol, timeframe, period + 50) # Get extra data for accuracy

if prices is None or len(prices) < period + 1:
    logging.warning(f"Insufficient price data for RSI calculation on {symbol}")
    if return_value:

    return 'hold'

# Calculate RSI
rsi_value = calculate_rsi(prices, period)

# Generate signal
if rsi_value <= oversold:
    signal = 'buy'
elif rsi_value >= overbought:
    signal = 'sell'
else:
    signal = 'hold'

logging.debug(f"RSI Signal for {symbol}: RSI={rsi_value:.2f}, Signal={signal}")

if return_value:
    return signal, rsi_value
return signal

except Exception as e:
    logging.error(f"Error calculating RSI signal for {symbol}: {e}")
    if return_value:
        return 'hold', 50.0
    return 'hold'

def get_rsi_value(symbol: str, timeframe: int=mt5.TIMEFRAME_M5, period: int=14) -> float

```

Get current RSI value for symbol Args: symbol: Trading symbol timeframe: MT5 timeframe constant period: RSI calculation period Returns: Current RSI value

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., symbol: str, timeframe: int, period: int). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type -> float. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def get_rsi_value(symbol: str, timeframe: int = mt5.TIMEFRAME_M5, period: int = 14) -> float:
    """
    Get current RSI value for symbol

    Args:
        symbol: Trading symbol
        timeframe: MT5 timeframe constant
        period: RSI calculation period

    Returns:
        Current RSI value
    """
    try:
        prices = get_price_data(symbol, timeframe, period + 50)

        if prices is None or len(prices) < period + 1:
            return 50.0

        return calculate_rsi(prices, period)

    except Exception as e:
        logging.error(f"Error getting RSI value for {symbol}: {e}")
        return 50.0
```

Step 6.5 — Build trader_companion/signals/macd.py

What to do. Create the file trader_companion/signals/macd.py in your project root and paste in the code shown in this step. The file is **42** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from requirements.txt.

trader_companion/signals/macd.py

42 loc · 0 classes · 1 functions · 3 imports

Single-indicator module — see the signals folder note above. Most of the work is a pandas computation feeding off OHLC bars. It defines **1** module-level function, across **42** lines.

Python concepts demonstrated in this module

- Comprehensions
- Exceptions

Imports — what each one is for

import MetaTrader5 as mt5

Why imported. Official MetaQuotes Python API for MT5. Connects to a local terminal, places orders, reads tick/bar history.

Used in this file. mt5.copy_rates_from_pos

Example. `mt5.initialize(); mt5.order_send(request)`

Other common scenarios.

- `mt5.symbols_get()` / `mt5.symbol_info(symbol)`
- `mt5.history_deals_get(from_, to_)` returns closed deals
- `mt5.account_info()` returns balance/equity/currency
- Always `mt5.shutdown()` in a finally to release the terminal

```
import pandas as pd
```

Why imported. DataFrame library — the workhorse for tabular data: loading CSV/Excel/SQL, joins, aggregations, time-series.

Used in this file. `pd.Series`

Example. `df = pd.read_csv(path); df.groupby('symbol')['pnl'].sum()`

Other common scenarios.

- `df.merge(other, on='key')` joins like SQL
- `df.resample('1D').agg(...)` for time-series rebucketing
- `df.to_sql` / `df.to_excel` / `df.to_parquet` for output
- `df.loc[mask, 'col']` for label-based selection/assignment

```
import numpy as np
```

Why imported. N-dimensional arrays — vectorised numerical computation. Backs pandas; used directly for indicator math.

Used in this file. `np.array`

Example. `np.where(close > open, 1, -1)` # vectorised conditional

Other common scenarios.

- Broadcasting: `arr * scalar`, `arr + arr2` work element-wise
- `np.nan` / `np.isnan(x)` for missing values
- `np.array(list)` creates a typed array; choose dtype carefully

Functions

```
def get_macd_signal(symbol, timeframe, fast_period=12, slow_period=26, signal_period=9, return_value=False):
```

Get MACD signal for a given symbol and timeframe. Args: symbol: Trading symbol timeframe: MT5 timeframe fast_period: Fast EMA period slow_period: Slow EMA period signal_period: Signal line EMA period return_value: If True, returns (signal, macd, signal_line) tuple, otherwise just signal Returns: If return_value=False: signal string ("buy", "sell", or None) If return_value=True: tuple (signal, macd, signal_line)

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't

have to handle it.

- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def get_macd_signal(symbol, timeframe, fast_period=12, slow_period=26, signal_period=9, return_value=False):
    """
    Get MACD signal for a given symbol and timeframe.
    Args:
        symbol: Trading symbol
        timeframe: MT5 timeframe
        fast_period: Fast EMA period
        slow_period: Slow EMA period
        signal_period: Signal line EMA period
        return_value: If True, returns (signal, macd, signal_line) tuple, otherwise just signal
    Returns:
        If return_value=False: signal string ("buy", "sell", or None)
        If return_value=True: tuple (signal, macd, signal_line)
    """
    try:
        rates = mt5.copy_rates_from_pos(symbol, timeframe, 0, slow_period + signal_period + 10)
        if rates is None or len(rates) < slow_period + signal_period:
            return None
        closes = np.array([rate[4] for rate in rates])
        fast_ema = pd.Series(closes).ewm(span=fast_period, adjust=False).mean()
        slow_ema = pd.Series(closes).ewm(span=slow_period, adjust=False).mean()
        macd = fast_ema - slow_ema
        signal_line = macd.ewm(span=signal_period, adjust=False).mean()
        # Use the last value for signal
        macd_val = macd.iloc[-1]
        signal_val = signal_line.iloc[-1]
        if macd_val > signal_val:
            signal = "buy"
        elif macd_val < signal_val:
            signal = "sell"
        else:
            signal = None
        if return_value:
            return signal, macd_val, signal_val
        return signal
    except Exception:
        return None
```

Step 6.6 — Build trader_companion/signals/bb.py

What to do. Create the file `trader_companion/signals/bb.py` in your project root and paste in the code shown in this step. The file is **38** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

trader_companion/signals/bb.py

38 loc · 0 classes · 1 functions · 3 imports

Single-indicator module — see the signals folder note above. Most of the work is a pandas computation feeding off OHLC bars. It defines **1** module-level function, across **38** lines.

Python concepts demonstrated in this module

- Comprehensions
- Exceptions

Imports — what each one is for

```
import MetaTrader5 as mt5
```

Why imported. Official MetaQuotes Python API for MT5. Connects to a local terminal, places orders, reads tick/bar history.

Used in this file. `mt5.copy_rates_from_pos`

Example. `mt5.initialize(); mt5.order_send(request)`

Other common scenarios.

- `mt5.symbols_get()` / `mt5.symbol_info(symbol)`

        sma = series.rolling(window=period).mean().iloc[-1]
        std = series.rolling(window=period).std().iloc[-1]
```

```

upper = sma + deviation * std
lower = sma - deviation * std
close = closes[-1]
signal = None
if close > upper:
    signal = "upper"
elif close < lower:
    signal = "lower"
if return_value:
    return signal, upper, lower, close
return signal
except Exception:
    return None

```

Step 6.7 — Build trader_companion/signals/atr.py

What to do. Create the file trader_companion/signals/atr.py in your project root and paste in the code shown in this step. The file is **30** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from requirements.txt.

trader_companion/signals/atr.py

30 loc · 0 classes · 1 functions · 3 imports

Single-indicator module — see the signals folder note above. Most of the work is a pandas computation feeding off OHLC bars. It defines **1** module-level function, across **30** lines.

Python concepts demonstrated in this module

- Comprehensions
- Exceptions

Imports — what each one is for

```
import MetaTrader5 as mt5
```

Why imported. Official MetaQuotes Python API for MT5. Connects to a local terminal, places orders, reads tick/bar history.

Used in this file. mt5.copy_rates_from_pos

Example. mt5.initialize(); mt5.order_send(request)

Other common scenarios.

- mt5.symbols_get() / mt5.symbol_info(symbol)
- mt5.history_deals_get(from_, to_) returns closed deals
- mt5.account_info() returns balance/equity/currency
- Always mt5.shutdown() in a finally to release the terminal

```

```
def get_atr_signal(symbol, timeframe, period=14, return_value=False):  
    """  
    Get Average True Range (ATR) value for a given symbol and timeframe.
```

```

Args:
    symbol: Trading symbol
    timeframe: MT5 timeframe
    period: ATR period
    return_value: If True, returns the ATR value
Returns:
    ATR value or None
"""
try:
    rates = mt5.copy_rates_from_pos(symbol, timeframe, 0, period + 2)
    if rates is None or len(rates) < period + 1:
        return None
    highs = np.array([rate[2] for rate in rates])
    lows = np.array([rate[3] for rate in rates])
    closes = np.array([rate[4] for rate in rates])
    trs = np.maximum(highs[1:] - lows[1:], np.abs(highs[1:] - closes[:-1]), np.abs(lows[1:] - closes[:-1]))
    atr = pd.Series(trs).rolling(window=period).mean().iloc[-1]
    if return_value:
        return atr
    return atr
except Exception:
    return None

```

Step 6.8 — Build `trader_companion/signals/adx.py`

What to do. Create the file `trader_companion/signals/adx.py` in your project root and paste in the code shown in this step. The file is **40** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

`trader_companion/signals/adx.py`

40 loc · 0 classes · 1 functions · 3 imports

Single-indicator module — see the signals folder note above. Most of the work is a pandas computation feeding off OHLC bars. It defines **1** module-level function, across **40** lines.

Python concepts demonstrated in this module

- Comprehensions
- Exceptions

Imports — *what each one is for*

```
import MetaTrader5 as mt5
```

Why imported. Official MetaQuotes Python API for MT5. Connects to a local terminal, places orders, reads tick/bar history.

Used in this file. `mt5.copy_rates_from_pos`

Example. `mt5.initialize(); mt5.order_send(request)`

Other common scenarios.

- `mt5.symbols_get()` / `mt5.symbol_info(symbol)`
- `mt5.history_deals_get(from_, to_)` returns closed deals
- `mt5.account_info()` returns balance/equity/currency
- Always `mt5.shutdown()` in a finally to release the terminal

```
import pandas as pd
```

Why imported. DataFrame library — the workhorse for tabular data: loading CSV/Excel/SQL, joins, aggregations, time-series.

Used in this file. `pd.Series`

Example. `df = pd.read_csv(path); df.groupby('symbol')['pnl'].sum()`

Other common scenarios.

- `df.merge(other, on='key')` joins like SQL
- `df.resample('1D').agg(...)` for time-series rebucketing
- `df.to_sql` / `df.to_excel` / `df.to_parquet` for output
- `df.loc[mask, 'col']` for label-based selection/assignment

```
import numpy as np
```

Why imported. N-dimensional arrays — vectorised numerical computation. Backs pandas; used directly for indicator math.

Used in this file. `np.abs`, `np.array`, `np.maximum`, `np.where`

Example. `np.where(close > open, 1, -1)` # vectorised conditional

Other common scenarios.

- Broadcasting: `arr * scalar`, `arr + arr2` work element-wise
- `np.nan` / `np.isnan(x)` for missing values
- `np.array(list)` creates a typed array; choose dtype carefully

Functions

```
def get_adx_signal(symbol, timeframe, period=14, threshold=25, return_value=False)
```

Get ADX value for a given symbol and timeframe. Args: symbol: Trading symbol timeframe: MT5 timeframe period: ADX period threshold: ADX threshold for trend strength return_value: If True, returns (signal, adx_value), else just signal Returns: Signal ("trend" or None) or (signal, adx_value)

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with `append`, and clearer about intent: this is a transform, not a side-effecting loop.
- **ternary expression** — Uses `x` if `cond` else `y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def get_adx_signal(symbol, timeframe, period=14, threshold=25, return_value=False):
    """
    Get ADX value for a given symbol and timeframe.
    Args:
        symbol: Trading symbol
        timeframe: MT5 timeframe
        period: ADX period
        threshold: ADX threshold for trend strength
        return_value: If True, returns (signal, adx_value), else just signal
    Returns:
        Signal ("trend" or None) or (signal, adx_value)
    """
    try:
        rates = mt5.copy_rates_from_pos(symbol, timeframe, 0, period + 50)
        if rates is None or len(rates) < period + 1:
            return None
        highs = np.array([rate[2] for rate in rates])
        lows = np.array([rate[3] for rate in rates])
        closes = np.array([rate[4] for rate in rates])
        plus_dm = highs[1:] - highs[:-1]
        minus_dm = lows[:-1] - lows[1:]
        plus_dm = np.where((plus_dm > minus_dm) & (plus_dm > 0), plus_dm, 0)
        minus_dm = np.where((minus_dm > plus_dm) & (minus_dm > 0), minus_dm, 0)
        tr = np.maximum(highs[1:] - lows[1:], np.abs(highs[1:] - closes[:-1]), np.abs(lows[1:] - closes[:-1]))
        atr = pd.Series(tr).rolling(window=period).mean()
        plus_di = 100 * pd.Series(plus_dm).rolling(window=period).mean() / atr
        minus_di = 100 * pd.Series(minus_dm).rolling(window=period).mean() / atr
        dx = 100 * np.abs(plus_di - minus_di) / (plus_di + minus_di)
        adx = pd.Series(dx).rolling(window=period).mean().iloc[-1]
        signal = "trend" if adx > threshold else None
        if return_value:
            return signal, adx
        return signal
    except Exception:
        return None
```

Step 6.9 — Build `trader_companion/signals/dmi.py`

What to do. Create the file `trader_companion/signals/dmi.py` in your project root and paste in the code shown in this step. The file is **42** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

trader_companion/signals/dmi.py

42 loc · 0 classes · 1 functions · 3 imports

Single-indicator module — see the signals folder note above. Most of the work is a pandas computation feeding off OHLC bars. It defines **1** module-level function, across **42** lines.

Python concepts demonstrated in this module

    return None

```

Step 6.13 — Build trader_companion/signals/obv.py

What to do. Create the file `trader_companion/signals/obv.py` in your project root and paste in the code shown in this step. The file is **35** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

trader_companion/signals/obv.py

35 loc · 0 classes · 1 functions · 3 imports

Single-indicator module — see the signals folder note above. Most of the work is a pandas computation feeding off OHLC bars. It defines **1** module-level function, across **35** lines.

Python concepts demonstrated in this module

- Comprehensions
- Exceptions

Imports — what each one is for

```
import MetaTrader5 as mt5
```

Why imported. Official MetaQuotes Python API for MT5. Connects to a local terminal, places orders, reads tick/bar history.

Used in this file. `mt5.copy_rates_from_pos`

Example. `mt5.initialize(); mt5.order_send(request)`

Other common scenarios.

- `mt5.symbols_get()` / `mt5.symbol_info(symbol)`
- `mt5.history_deals_get(from_, to_)` returns closed deals
- `mt5.account_info()` returns balance/equity/currency
- Always `mt5.shutdown()` in a finally to release the terminal

```
import pandas as pd
```

Why imported. DataFrame library — the workhorse for tabular data: loading CSV/Excel/SQL, joins, aggregations, time-series.

Used in this file. *No direct attribute access detected — likely imported for side effects, re-export, or string references.*

Example. `df = pd.read_csv(path); df.groupby('symbol')['pnl'].sum()`

Other common scenarios.

- `df.merge(other, on='key')` joins like SQL
- `df.resample('1D').agg(...)` for time-series rebucketing
- `df.to_sql` / `df.to_excel` / `df.to_parquet` for output
- `df.loc[mask, 'col']` for label-based selection/assignment

```
import numpy as np
```

Why imported. N-dimensional arrays — vectorised numerical computation. Backs pandas; used directly for indicator math.

Used in this file. `np.array`

Example. `np.where(close > open, 1, -1)` # vectorised conditional

Other common scenarios.

- Broadcasting: `arr * scalar`, `arr + arr2` work element-wise
- `np.nan` / `np.isnan(x)` for missing values
- `np.array(list)` creates a typed array; choose dtype carefully

Functions

```
def get_obv_signal(symbol, timeframe, return_value=False)
```

*Get On-Balance Volume (OBV) signal for a given symbol and timeframe. Args: symbol: Trading symbol
timeframe: MT5 timeframe return_value: If True, returns the OBV value Returns: OBV value or None*

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def get_obv_signal(symbol, timeframe, return_value=False):
    """
    Get On-Balance Volume (OBV) signal for a given symbol and timeframe.
    Args:
        symbol: Trading symbol
```

```

    timeframe: MT5 timeframe
    return_value: If True, returns the OBV value
Returns:
    OBV value or None
"""
try:
    rates = mt5.copy_rates_from_pos(symbol, timeframe, 0, 100)
    if rates is None or len(rates) < 2:
        return None
    closes = np.array([rate[4] for rate in rates])
    volumes = np.array([rate[5] for rate in rates])
    obv = [volumes[0]]
    for i in range(1, len(closes)):
        if closes[i] > closes[i-1]:
            obv.append(obv[-1] + volumes[i])
        elif closes[i] < closes[i-1]:
            obv.append(obv[-1] - volumes[i])
        else:
            obv.append(obv[-1])
    obv_value = obv[-1]
    if return_value:
        return obv_value
    return obv_value
except Exception:
    return None

```

Step 6.14 — Build trader_companion/signals/mfi.py

What to do. Create the file `trader_companion/signals/mfi.py` in your project root and paste in the code shown in this step. The file is **43** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

trader_companion/signals/mfi.py

43 loc · 0 classes · 1 functions · 3 imports

Single-indicator module — see the signals folder note above. Most of the work is a pandas computation feeding off OHLC bars. It defines **1** module-level function, across **43** lines.

Python concepts demonstrated in this module

- Comprehensions
- Exceptions

Imports — what each one is for

```
import MetaTrader5 as mt5
```

Why imported. Official MetaQuotes Python API for MT5. Connects to a local terminal, places orders, reads tick/bar history.

Used in this file. `mt5.copy_rates_from_pos`

Example. `mt5.initialize(); mt5.order_send(request)`

Other common scenarios.

- `mt5.symbols_get()` / `mt5.symbol_info(symbol)`
- `mt5.history_deals_get(from_, to_)` returns closed deals
- `mt5.account_info()` returns balance/equity/currency
- Always `mt5.shutdown()` in a finally to release the terminal

```
import pandas as pd
```

Why imported. DataFrame library — the workhorse for tabular data: loading CSV/Excel/SQL, joins, aggregations, time-series.

Used in this file. `pd.Series`

Example. `df = pd.read_csv(path); df.groupby('symbol')['pnl'].sum()`

Other common scenarios.

- `df.merge(other, on='key')` joins like SQL
- `df.resample('1D').agg(...)` for time-series rebucketing
- `df.to_sql` / `df.to_excel` / `df.to_parquet` for output
- `df.loc[mask, 'col']` for label-based selection/assignment

```
import numpy as np
```

Why imported. N-dimensional arrays — vectorised numerical computation. Backs pandas; used directly for indicator math.

Used in this file. `np.array`, `np.where`

Example. `np.where(close > open, 1, -1)` # vectorised conditional

Other common scenarios.

- Broadcasting: `arr * scalar`, `arr + arr2` work element-wise
- `np.nan` / `np.isnan(x)` for missing values
- `np.array(list)` creates a typed array; choose dtype carefully

Functions

```
def get_mfi_signal(symbol, timeframe, period=14, overbought=80, oversold=20, return_value=False)
```

*Get Money Flow Index (MFI) signal for a given symbol and timeframe. Args: symbol: Trading symbol
timeframe: MT5 timeframe period: MFI period overbought: Overbought threshold oversold: Oversold
threshold return_value: If True, returns (signal, mfi_value), else just signal Returns: Signal ("buy", "sell",
or None) or (signal, mfi_value)*

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't

have to handle it.

- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **ternary expression** — Uses `x` if `cond` else `y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. try block with 1 **except** clause.

Code (copy-paste safe)

```
def get_mfi_signal(symbol, timeframe, period=14, overbought=80, oversold=20, return_value=False):
    """
    Get Money Flow Index (MFI) signal for a given symbol and timeframe.
    Args:
        symbol: Trading symbol
        timeframe: MT5 timeframe
        period: MFI period
        overbought: Overbought threshold
        oversold: Oversold threshold
        return_value: If True, returns (signal, mfi_value), else just signal
    Returns:
        Signal ("buy", "sell", or None) or (signal, mfi_value)
    """
    try:
        rates = mt5.copy_rates_from_pos(symbol, timeframe, 0, period + 10)
        if rates is None or len(rates) < period + 1:
            return None
        highs = np.array([rate[2] for rate in rates])
        lows = np.array([rate[3] for rate in rates])
        closes = np.array([rate[4] for rate in rates])
        volumes = np.array([rate[5] for rate in rates])
        typical_price = (highs + lows + closes) / 3
        money_flow = typical_price * volumes
        positive_flow = np.where(typical_price[1:] > typical_price[:-1], money_flow[1:], 0)
        negative_flow = np.where(typical_price[1:] < typical_price[:-1], money_flow[1:], 0)
        pos_mf = pd.Series(positive_flow).rolling(window=period).sum().iloc[-1]
        neg_mf = pd.Series(negative_flow).rolling(window=period).sum().iloc[-1]
        mfi = 100 * pos_mf / (pos_mf + neg_mf) if (pos_mf + neg_mf) != 0 else 50
        signal = None
        if mfi > overbought:
            signal = "sell"
        elif mfi < oversold:
            signal = "buy"
        if return_value:
            return signal, mfi
        return signal
    except Exception:
        return None
```

Step 6.15 — Build trader_companion/signals/stochastic.py

What to do. Create the file `trader_companion/signals/stochastic.py` in your project root and paste in the code shown in this step. The file is **42** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

trader_companion/signals/stochastic.py

42 loc · 0 classes · 1 functions · 3 imports

Single-indicator module — see the signals folder note above. Most of the work is a pandas computation feeding off OHLC bars. It defines **1** module-level function, across **42** lines.

Python concepts demonstrated in this module

- `df.loc[mask, 'col']` for label-based selection/assignment

```
import numpy as np
```

Why imported. N-dimensional arrays — vectorised numerical computation. Backs pandas; used directly for indicator math.

Used in this file. `np.abs`, `np.array`, `np.maximum`, `np.ones_like`, `np.zeros_like`

Example. `np.where(close > open, 1, -1)` # vectorised conditional

Other common scenarios.

- Broadcasting: `arr * scalar`, `arr + arr2` work element-wise
- `np.nan` / `np.isnan(x)` for missing values
- `np.array(list)` creates a typed array; choose dtype carefully

Functions

```
def get_supertrend_signal(symbol, timeframe, period=10, multiplier=3.0, return_value=False)
```

Get Supertrend signal for a given symbol and timeframe. Args: symbol: Trading symbol timeframe: MT5 timeframe period: ATR period for Supertrend multiplier: Multiplier for ATR return_value: If True, returns (signal, supertrend), else just signal Returns: Signal ("bullish", "bearish", or None) or (signal, supertrend)

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.

• **ternary expression** — Uses `x` if `cond` else `y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. `try` block with 1 `except` clause.

Code (copy-paste safe)

```
def get_supertrend_signal(symbol, timeframe, period=10, multiplier=3.0, return_value=False):
    """
    Get Supertrend signal for a given symbol and timeframe.
    Args:
        symbol: Trading symbol
        timeframe: MT5 timeframe
        period: ATR period for Supertrend
        multiplier: Multiplier for ATR
        return_value: If True, returns (signal, supertrend), else just signal
    Returns:
        Signal ("bullish", "bearish", or None) or (signal, supertrend)
    """
    try:
        rates = mt5.copy_rates_from_pos(symbol, timeframe, 0, period + 10)
        if rates is None or len(rates) < period + 1:
            return None
        highs = np.array([rate[2] for rate in rates])
        lows = np.array([rate[3] for rate in rates])
        closes = np.array([rate[4] for rate in rates])
        atr = pd.Series(np.maximum(highs[1:] - lows[1:], np.abs(highs[1:] - closes[:-1]), np.abs(lows[1:] - closes[:-1]))).rolling(window=period).mean()
        hl2 = (highs + lows) / 2
        upperband = hl2 - (multiplier * atr)
        lowerband = hl2 + (multiplier * atr)
        supertrend = np.zeros_like(closes)
        direction = np.ones_like(closes)
        for i in range(1, len(closes)):
            if closes[i] > upperband[i]:
                direction[i] = 1
            elif closes[i] < lowerband[i]:
                direction[i] = -1
            else:
                direction[i] = direction[i-1]
            supertrend[i] = lowerband[i] if direction[i] == 1 else upperband[i]
        signal = "bullish" if direction[-1] == 1 else "bearish"
        if return_value:
            return signal, supertrend[-1]
        return signal
    except Exception:
        return None
```

Step 6.17 — Build `trader_companion/signals/sar.py`

What to do. Create the file `trader_companion/signals/sar.py` in your project root and paste in the code shown in this step. The file is **56** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

trader_companion/signals/sar.py

56 loc · 0 classes · 1 functions · 3 imports

Single-indicator module — see the signals folder note above. Most of the work is a pandas computation feeding off OHLC bars. It defines **1** module-level function, across **56** lines.

Python concepts demonstrated in this module

                ep = highs[i]
                af = step
    sar_value = sar[-1]
    signal = "buy" if closes[-1] > sar_value else "sell"
    if return_value:
        return signal, sar_value
    return signal
except Exception:
    return None

```

Step 6.18 — Build trader_companion/signals/tsi.py

What to do. Create the file `trader_companion/signals/tsi.py` in your project root and paste in the code shown in this step. The file is **39** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

trader_companion/signals/tsi.py

39 loc · 0 classes · 1 functions · 3 imports

Single-indicator module — see the signals folder note above. Most of the work is a pandas computation feeding off OHLC bars. It defines **1** module-level function, across **39** lines.

Python concepts demonstrated in this module

- Comprehensions
- Exceptions

Imports — what each one is for

```
import MetaTrader5 as mt5
```

Why imported. Official MetaQuotes Python API for MT5. Connects to a local terminal, places orders, reads tick/bar history.

Used in this file. `mt5.copy_rates_from_pos`

Example. `mt5.initialize(); mt5.order_send(request)`

Other common scenarios.

- `mt5.symbols_get()` / `mt5.symbol_info(symbol)`
- `mt5.history_deals_get(from_, to_)` returns closed deals
- `mt5.account_info()` returns balance/equity/currency
- Always `mt5.shutdown()` in a finally to release the terminal

```
import pandas as pd
```

Why imported. DataFrame library — the workhorse for tabular data: loading CSV/Excel/SQL, joins, aggregations, time-series.

Used in this file. `pd.Series`

Example. `df = pd.read_csv(path); df.groupby('symbol')['pnl'].sum()`

Other common scenarios.

- `df.merge(other, on='key')` joins like SQL
- `df.resample('1D').agg(...)` for time-series rebucketing
- `df.to_sql` / `df.to_excel` / `df.to_parquet` for output
- `df.loc[mask, 'col']` for label-based selection/assignment

```
import numpy as np
```

Why imported. N-dimensional arrays — vectorised numerical computation. Backs pandas; used directly for indicator math.

Used in this file. `np.abs`, `np.array`, `np.diff`

Example. `np.where(close > open, 1, -1)` # vectorised conditional

Other common scenarios.

- Broadcasting: `arr * scalar`, `arr + arr2` work element-wise
- `np.nan` / `np.isnan(x)` for missing values
- `np.array(list)` creates a typed array; choose dtype carefully

Functions

```
def get_tsi_signal(symbol, timeframe, r=25, s=13, return_value=False)
```

*Get True Strength Index (TSI) signal for a given symbol and timeframe. Args: symbol: Trading symbol
timeframe: MT5 timeframe r: Long EMA period s: Short EMA period return_value: If True, returns (signal, tsi_value), else just signal Returns: Signal ("bullish", "bearish", or None) or (signal, tsi_value)*

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression ([f(x) for x in xs]). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def get_tsi_signal(symbol, timeframe, r=25, s=13, return_value=False):
    """
    Get True Strength Index (TSI) signal for a given symbol and timeframe.
    Args:
        symbol: Trading symbol
        timeframe: MT5 timeframe
        r: Long EMA period
        s: Short EMA period
        return_value: If True, returns (signal, tsi_value), else just signal
    Returns:
        Signal ("bullish", "bearish", or None) or (signal, tsi_value)
    """
    try:
        rates = mt5.copy_rates_from_pos(symbol, timeframe, 0, r + s + 10)
        if rates is None or len(rates) < r + s:
            return None
        closes = np.array([rate[4] for rate in rates])
        diff = np.diff(closes)
        abs_diff = np.abs(diff)
        ema1 = pd.Series(diff).ewm(span=s, adjust=False).mean()
        ema2 = ema1.ewm(span=r, adjust=False).mean()
        abs_ema1 = pd.Series(abs_diff).ewm(span=s, adjust=False).mean()
        abs_ema2 = abs_ema1.ewm(span=r, adjust=False).mean()
        tsi = 100 * (ema2.iloc[-1] / abs_ema2.iloc[-1]) if abs_ema2.iloc[-1] != 0 else 0
        signal = None
        if tsi > 25:
            signal = "bullish"
        elif tsi < -25:
            signal = "bearish"
        if return_value:
            return signal, tsi
        return signal
    except Exception:
        return None
```

Step 6.19 — Build trader_companion/signals/wr.py

What to do. Create the file `trader_companion/signals/wr.py` in your project root and paste in the code shown in this step. The file is **38** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

trader_companion/signals/wr.py

38 loc · 0 classes · 1 functions · 3 imports

Single-indicator module — see the signals folder note above. Most of the work is a pandas computation feeding off OHLC bars. It defines **1** module-level function, across **38** lines.

Python concepts demonstrated in this module

- Comprehensions
- Exceptions

Imports — what each one is for

```
import MetaTrader5 as mt5
```

Why imported. Official MetaQuotes Python API for MT5. Connects to a local terminal, places orders, reads tick/bar history.

Used in this file. `mt5.copy_rates_from_pos`

Example. `mt5.initialize(); mt5.order_send(request)`

Other common scenarios.

- `mt5.symbols_get()` / `mt5.symbol_info(symbol)`
- `mt5.history_deals_get(from_, to_)` returns closed deals
- `mt5.account_info()` returns balance/equity/currency
- Always `mt5.shutdown()` in a finally to release the terminal

```
import pandas as pd
```

Why imported. DataFrame library — the workhorse for tabular data: loading CSV/Excel/SQL, joins, aggregations, time-series.

Used in this file. *No direct attribute access detected — likely imported for side effects, re-export, or string references.*

Example. `df = pd.read_csv(path); df.groupby('symbol')['pnl'].sum()`

Other common scenarios.

- `df.merge(other, on='key')` joins like SQL

- `df.resample('1D').agg(...)` for time-series rebucketing
- `df.to_sql` / `df.to_excel` / `df.to_parquet` for output
- `df.loc[mask, 'col']` for label-based selection/assignment

`import numpy as np`

Why imported. N-dimensional arrays — vectorised numerical computation. Backs pandas; used directly for indicator math.

Used in this file. `np.array`, `np.max`, `np.min`

Example. `np.where(close > open, 1, -1)` # vectorised conditional

Other common scenarios.

- Broadcasting: `arr * scalar`, `arr + arr2` work element-wise
- `np.nan` / `np.isnan(x)` for missing values
- `np.array(list)` creates a typed array; choose `dtype` carefully

Functions

```
def get_wr_signal(symbol, timeframe, period=14, overbought=-20, oversold=-80, return_value=False)
```

Get Williams %R signal for a given symbol and timeframe. Args: symbol: Trading symbol timeframe: MT5 timeframe period: WR period overbought: Overbought threshold oversold: Oversold threshold return_value: If True, returns (signal, wr_value), else just signal Returns: Signal ("buy", "sell", or None) or (signal, wr_value)

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with `append`, and clearer about intent: this is a transform, not a side-effecting loop.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def get_wr_signal(symbol, timeframe, period=14, overbought=-20, oversold=-80, return_value=False):
    """
    Get Williams %R signal for a given symbol and timeframe.
    Args:
        symbol: Trading symbol
        timeframe: MT5 timeframe
        period: WR period
        overbought: Overbought threshold
        oversold: Oversold threshold
        return_value: If True, returns (signal, wr_value), else just signal
    Returns:
        Signal ("buy", "sell", or None) or (signal, wr_value)
    """
    try:
```

```

rates = mt5.copy_rates_from_pos(symbol, timeframe, 0, period + 10)
if rates is None or len(rates) < period:
    return None
highs = np.array([rate[2] for rate in rates])
lows = np.array([rate[3] for rate in rates])
closes = np.array([rate[4] for rate in rates])
highest_high = np.max(highs[-period:])
lowest_low = np.min(lows[-period:])
wr = -100 * (highest_high - closes[-1]) / (highest_high - lowest_low)
signal = None
if wr > overbought:
    signal = "sell"
elif wr < oversold:
    signal = "buy"
if return_value:
    return signal, wr
return signal
except Exception:
    return None

```

Step 6.20 — Build trader_companion/signals/cmo.py

What to do. Create the file `trader_companion/signals/cmo.py` in your project root and paste in the code shown in this step. The file is **7** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

trader_companion/signals/cmo.py

7 loc · 0 classes · 1 functions · 1 imports

Single-indicator module — see the signals folder note above. Most of the work is a pandas computation feeding off OHLC bars. It defines **1** module-level function, across **7** lines.

Python concepts demonstrated in this module

- Type hints

Imports — what each one is for

```
import pandas as pd
```

Why imported. DataFrame library — the workhorse for tabular data: loading CSV/Excel/SQL, joins, aggregations, time-series.

Used in this file. `pd.DataFrame`

Example. `df = pd.read_csv(path); df.groupby('symbol')['pnl'].sum()`

Other common scenarios.

- `df.merge(other, on='key')` joins like SQL
- `df.resample('1D').agg(...)` for time-series rebucketing
- `df.to_sql` / `df.to_excel` / `df.to_parquet` for output
- `df.loc[mask, 'col']` for label-based selection/assignment

Functions

```
def get_cmo_signal(df: pd.DataFrame, period: int=14)
```

Why these Python concepts were used

• **type-annotated parameters** — Parameters carry type hints (e.g., `df: pd.DataFrame, period: int`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.

Step by step (top-level body)

1. `return 0`.

Code (copy-paste safe)

```
def get_cmo_signal(df: pd.DataFrame, period: int = 14):
    # Placeholder for Chande Momentum Oscillator (CMO) signal logic
    # Return 1 for buy, -1 for sell, 0 for neutral
    return 0
```

Step 6.21 — Build trader_companion/signals/coppock_curve.py

What to do. Create the file `trader_companion/signals/coppock_curve.py` in your project root and paste in the code shown in this step. The file is **7** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

trader_companion/signals/coppock_curve.py

7 loc · 0 classes · 1 functions · 1 imports

Single-indicator module — see the signals folder note above. Most of the work is a pandas computation feeding off OHLC bars. It defines **1** module-level function, across **7** lines.

Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.

Step by step (top-level body)

1. `return 0`.

Code (copy-paste safe)

```
def get_price_channel_signal(df: pd.DataFrame, period: int = 20):
    # Placeholder for Price Channel signal logic
    # Return 1 for buy, -1 for sell, 0 for neutral
    return 0
```

Step 6.28 — Build trader_companion/signals/ultimate_oscillator.py

What to do. Create the file `trader_companion/signals/ultimate_oscillator.py` in your project root and paste in the code shown in this step. The file is **7** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

trader_companion/signals/ultimate_oscillator.py

7 loc · 0 classes · 1 functions · 1 imports

Single-indicator module — see the signals folder note above. Most of the work is a pandas computation feeding off OHLC bars. It defines **1** module-level function, across **7** lines.

Python concepts demonstrated in this module

- Type hints

Imports — what each one is for

```
import pandas as pd
```

Why imported. DataFrame library — the workhorse for tabular data: loading CSV/Excel/SQL, joins, aggregations, time-series.

Used in this file. `pd.DataFrame`

Example. `df = pd.read_csv(path); df.groupby('symbol')['pnl'].sum()`

Other common scenarios.

- `df.merge(other, on='key')` joins like SQL
- `df.resample('1D').agg(...)` for time-series rebucketing
- `df.to_sql` / `df.to_excel` / `df.to_parquet` for output
- `df.loc[mask, 'col']` for label-based selection/assignment

Functions

```
def get_ultimate_oscillator_signal(df: pd.DataFrame)
```

Why these Python concepts were used

• **type-annotated parameters** — Parameters carry type hints (e.g., `df: pd.DataFrame`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.

Step by step (top-level body)

1. `return 0.`

Code (copy-paste safe)

```
def get_ultimate_oscillator_signal(df: pd.DataFrame):
    # Placeholder for Ultimate Oscillator signal logic
    # Return 1 for buy, -1 for sell, 0 for neutral
    return 0
```

Step 6.29 — Build trader_companion/signals/vortex.py

What to do. Create the file `trader_companion/signals/vortex.py` in your project root and paste in the code shown in this step. The file is **7** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

trader_companion/signals/vortex.py

7 loc · 0 classes · 1 functions · 1 imports

Single-indicator module — see the `signals` folder note above. Most of the work is a pandas computation feeding off OHLC bars. It defines **1** module-level function, across **7** lines.

Python concepts demonstrated in this module

- Type hints

Imports — what each one is for

```
import pandas as pd
```

Why imported. DataFrame library — the workhorse for tabular data: loading CSV/Excel/SQL, joins, aggregations, time-series.

Used in this file. `pd.DataFrame`

Example. `df = pd.read_csv(path); df.groupby('symbol')['pnl'].sum()`

Other common scenarios.

- `df.merge(other, on='key')` joins like SQL
- `df.resample('1D').agg(...)` for time-series rebucketing
- `df.to_sql` / `df.to_excel` / `df.to_parquet` for output
- `df.loc[mask, 'col']` for label-based selection/assignment

Functions

```
def get_vortex_signal(df: pd.DataFrame, period: int=14)
```

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `df: pd.DataFrame, period: int`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.

Step by step (top-level body)

1. `return 0`.

Code (copy-paste safe)

```
def get_vortex_signal(df: pd.DataFrame, period: int = 14):
    # Placeholder for Vortex Indicator signal logic
    # Return 1 for buy, -1 for sell, 0 for neutral
    return 0
```

Step 6.30 — Build `trader_companion/strategies/__init__.py`

What to do. Create the file `trader_companion/strategies/__init__.py` in your project root and paste in the code shown in this step. The file is **2** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

`trader_companion/strategies/__init__.py`

2 loc · 0 classes · 0 functions · 0 imports

Package marker. Importing this folder as a module runs the code here (often empty, sometimes used to re-export public names). across **2** lines.

Step 6.31 — Build `trader_companion/strategies/rsi_overbought_oversold.py`

What to do. Create the file `trader_companion/strategies/rsi_overbought_oversold.py` in your project root and paste in the code shown in this step. The file is **22** lines long; we walk through it piece by piece below.

Depends on. This file imports from internal modules built in earlier steps: `signals`. If any of those imports fail, jump back to the step that introduced them.

`trader_companion/strategies/rsi_overbought_oversold.py`

22 loc · 0 classes · 1 functions · 1 imports

It defines **1** module-level function, across **22** lines.

Imports — what each one is for

```
from signals.rsi import get_rsi_signal
```

Why imported. Sub-package of `trader_companion` — one technical indicator per file.

Used in this file. `get_rsi_signal`

Functions

```
def rsi_overbought_oversold_strategy(symbol, timeframe, rsi_period=14, rsi_overbought=70, rsi_oversold=30,
    risk_percent=2.0, return_value=False)
```

RSI Overbought/Oversold strategy logic. User-editable parameters: `rsi_period`: int - RSI calculation period `rsi_overbought`: int/float - Overbought threshold `rsi_oversold`: int/float - Oversold threshold `risk_percent`: float - Risk per trade (not used in signal, but available for position sizing) Returns: 'buy', 'sell', or None (or tuple with RSI value if `return_value=True`)

Step by step (top-level body)

1. `return get_rsi_signal(symbol=symbol, timeframe=timeframe, period=rsi_perio....`

Code (copy-paste safe)

```
def rsi_overbought_oversold_strategy(symbol, timeframe, rsi_period=14, rsi_overbought=70, rsi_oversold=30,
    risk_percent=2.0, return_value=False):
    """
    RSI Overbought/Oversold strategy logic.
    User-editable parameters:
        rsi_period: int - RSI calculation period
        rsi_overbought: int/float - Overbought threshold
        rsi_oversold: int/float - Oversold threshold
        risk_percent: float - Risk per trade (not used in signal, but available for position sizing)
    Returns:
        'buy', 'sell', or None (or tuple with RSI value if return_value=True)
    """
    return get_rsi_signal(
        symbol=symbol,
        timeframe=timeframe,
        period=rsi_period,
        overbought=rsi_overbought,
        oversold=rsi_oversold,
        return_value=return_value
    )
```

Checkpoint — what works now. Indicator math works in isolation. Feed any indicator function a small DataFrame of OHLC bars and inspect the output Series. The strategy in `strategies/rsi_overbought_oversold.py` can now decide buy/sell on synthetic data — but it has nothing to send the decision to yet. That is the next phase.

Chapter 7 — Phase 5 — The trading engine

Now we wire the signals and the MT5 connector together. `mt5_trading.py` sends orders and reads positions; `mt5_comment_parser.py` tags those orders with structured strategy metadata; `trade_limit_manager.py` enforces the daily loss/position-size guardrails; and `hedge_protector.py` opens offsetting positions on a hedge account so that drawdown on the funded leg is bounded. This is the heart of the system.

Files we build in this phase, in order:

- `trader_companion/mt5_trading.py`
- `trader_companion/mt5_comment_parser.py`
- `trader_companion/trade_limit_manager.py`
- `trader_companion/hedge_protector.py`

Python concepts you'll meet in this phase

- Dunder methods (4) · Classes and objects (4) · f-strings (4) · Exceptions (4) · Lambdas (3)
- Comprehensions (2) · Context managers (with-statements) (2) · Properties (2)

Each is explained in Chapter 2 (the primer). The number in parentheses is how many of this phase's files use that concept.

Step 7.1 — Build `trader_companion/mt5_trading.py`

What to do. Create the file `trader_companion/mt5_trading.py` in your project root and paste in the code shown in this step. The file is **2485** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

What this file is for. All MetaTrader 5 trading helpers: order submission, position lookup, fill reconciliation. Wraps the official MetaTrader5 Python package.

`trader_companion/mt5_trading.py`

2485 loc · 1 classes · 2 functions · 12 imports

All MetaTrader 5 trading helpers: order submission, position lookup, fill reconciliation. Wraps the official MetaTrader5 Python package. It defines **1** class and **2** module-level functions, across **2,485** lines.

Python concepts demonstrated in this module

• Classes and objects • Comprehensions • Context managers (with-statements) • Dunder methods • Exceptions • f-strings • Lambdas

Imports — what each one is for

```
import sys
```

Why imported. Access to the running interpreter — argv, stdin/stdout, exit codes, the import search path, and the platform name.

Used in this file. sys._MEIPASS

Example. sys.exit(1) # terminate the process with a non-zero status

Other common scenarios.

- sys.argv[1:] reads the command-line arguments
- sys.path.insert(0, 'extra') prepends to the import search path
- sys.stderr.write(msg) writes to standard error
- sys.platform tells you 'win32', 'linux', or 'darwin'
- sys.modules is the global cache of already-imported modules

```
import os
```

Why imported. Operating-system interface. Path manipulation, environment variables, working-directory operations, exit codes, and thin wrappers around POSIX/Windows syscalls.

Used in this file. os.add_dll_directory, os.environ, os.environ.get, os.getenv, os.path, os.path.abspath, os.path.basename, os.path.dirname

Example. os.path.join(root, 'subdir', 'file.txt') # joins with the OS-correct separator

Other common scenarios.

- os.environ.get('API_KEY') to read environment variables
- os.makedirs(path, exist_ok=True) to create nested directories
- os.listdir(path) to list a directory's contents
- os.remove(path) / os.rename(src, dst) to delete or move a file
- os.getcwd() / os.chdir(path) to inspect or change the working dir

```
import winreg
```

Why imported. Read and write the Windows registry — used to discover installed MetaTrader terminals.

Used in this file. winreg.EnumKey, winreg.HKEY_CURRENT_USER, winreg.HKEY_LOCAL_MACHINE, winreg.OpenKey, winreg.QueryValueEx

Example. winreg.OpenKey(HKEY_LOCAL_MACHINE, r'Software\\X')

Other common scenarios.

- QueryValueEx returns a (value, type) tuple
- EnumKey / EnumValue iterate sub-keys

```
from pathlib import Path
```

Why imported. Object-oriented filesystem paths. Replaces most uses of os.path with chainable methods and operator overloading.

Used in this file. *No direct attribute access detected — likely imported for side effects, re-export, or string references.*

Example. Path('logs') / f'{name}.log' # / is overloaded to join

Other common scenarios.

- p.exists(), p.is_file(), p.is_dir() for predicates
- p.read_text() / p.write_text(content) for one-shot file I/O
- p.glob('**/*.py') to walk a tree with a pattern
- p.with_suffix('.bak') to derive a sibling path

```
from dotenv import load_dotenv
```

Why imported. python-dotenv — load .env files into os.environ for twelve-factor configuration in development.

Used in this file. load_dotenv

Example. load_dotenv() # call once at process start

Other common scenarios.

- dotenv_values('.env') returns a dict without polluting os.environ
- Use a real secret store in production (vault, AWS SM, etc.)

```
import logging
```

Why imported. Structured, levelled logging. Replaces print() with filterable, formattable output that can route to files, stderr, syslog, or HTTP endpoints.

Used in this file. logging.INFO, logging.basicConfig, logging.debug, logging.error, logging.exception, logging.info, logging.warning

Example. logging.getLogger(__name__).info('connected to %s', host)

Other common scenarios.

- .debug() / .info() / .warning() / .error() / .exception()
- logger.exception() captures the current traceback automatically
- logging.basicConfig(level=logging.INFO) for quick setup
- Handlers and Formatters route logs to files / streams / syslog

```
import subprocess
```

Why imported. Run external programs. The standard way to spawn a child process, capture its output, and wait for its exit code.

Used in this file. subprocess.run

Example. subprocess.run(['git', 'rev-parse', 'HEAD'], capture_output=True, text=True, check=True)

Other common scenarios.

- Popen(...) for streaming I/O while the process is alive
- check_output(cmd) returns stdout as text and raises on failure
- DEVNULL / PIPE redirect stdin/stdout/stderr
- shell=True interprets the string with the system shell (security risk)

import psutil

Why imported. Cross-platform process and system information — find a running terminal, check CPU/memory, kill a stale process.

Used in this file. psutil.AccessDenied, psutil.NoSuchProcess, psutil.ZombieProcess, psutil.disk_partitions, psutil.process_iter

Example. psutil.process_iter(['name']) # iterate live processes

Other common scenarios.

- psutil.Process(pid).terminate() / .kill()
- psutil.cpu_percent(interval=1.0) measures CPU usage
- psutil.virtual_memory() returns RAM stats

import time

Why imported. Timestamps and sleep. Lower-level than datetime — works in Unix-epoch seconds.

Used in this file. time.sleep, time.time

Example. time.sleep(1.5) # pause this thread for 1.5 seconds

Other common scenarios.

- time.time() returns seconds since the epoch
- time.monotonic() for measuring elapsed time (never goes backward)
- time.perf_counter() for high-precision benchmarking
- time.strptime / time.strftime mirror the datetime versions

from time import sleep

Why imported. Timestamps and sleep. Lower-level than datetime — works in Unix-epoch seconds.

Used in this file. sleep

Example. time.sleep(1.5) # pause this thread for 1.5 seconds

Other common scenarios.

- time.time() returns seconds since the epoch
- time.monotonic() for measuring elapsed time (never goes backward)
- time.perf_counter() for high-precision benchmarking

- `time.strptime / time.strptime` mirror the `datetime` versions

```
import ctypes
```

Why imported. Call C functions from shared libraries (DLLs / `.so` / `.dylib`). Used here to reach Win32 APIs the `stdlib` doesn't expose.

Used in this file. *No direct attribute access detected — likely imported for side effects, re-export, or string references.*

Example. `ctypes.windll.user32.MessageBoxW(0, 'hi', 't', 0)`

Other common scenarios.

- `CDLL('libfoo.so')` loads a Unix shared object
- Define `argtypes/restype` to get type-checked calls
- `c_int / c_char_p` / Structure mirror C type layouts

```
from ctypes import wintypes
```

Why imported. Call C functions from shared libraries (DLLs / `.so` / `.dylib`). Used here to reach Win32 APIs the `stdlib` doesn't expose.

Used in this file. *No direct attribute access detected — likely imported for side effects, re-export, or string references.*

Example. `ctypes.windll.user32.MessageBoxW(0, 'hi', 't', 0)`

Other common scenarios.

- `CDLL('libfoo.so')` loads a Unix shared object
- Define `argtypes/restype` to get type-checked calls
- `c_int / c_char_p` / Structure mirror C type layouts

Classes

```
class MT5API
    _symbol_cache = {}
    _symbol_cache_timestamp = {}
    _cache_ttl = 300
```

Code (copy-paste safe)

```
class MT5API:
    # Class-level symbol cache to persist across instances
    _symbol_cache = {}
    _symbol_cache_timestamp = {}
    _cache_ttl = 300 # Cache for 5 minutes

    def __init__(self, login, password, server, symbol=None, terminal_path=None):

```

Method: MT5API.__init__

```
def __init__(self, login, password, server, symbol=None, terminal_path=None)
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.
- **__init__** — The constructor. Runs after Python has allocated the instance; assigns starting attribute values to self.

Step by step (top-level body)

1. **try** block with 1 **except** clause.
2. Assigns `self.password = str(password) if password else "`.
3. Assigns `self.server = str(server) if server else "`.
4. Assigns `self.symbol = symbol`.
5. Assigns `self.terminal_path = terminal_path`.

6. Assigns `self.sl_points = float(os.getenv('MT5_SL_POINTS') or os.getenv('MT5_STOPLO....`
7. Assigns `self.tp_points = float(os.getenv('MT5_TP_POINTS') or os.getenv('MT5_TAKEPR....`
8. Assigns `self.default_volume = float(os.getenv('MT5_VOLUME', '1'))`.
9. Assigns `self.rollover_executed_today = {}`.
10. Assigns `self.connected_symbol = None`.
11. Assigns `self.is_plexy_server = 'plexy' in server.lower()` if server else False.
12. **if** `self.is_plexy_server`: branches conditionally.
13. Assigns `self.connected = False`.
14. Assigns `self.last_error = None`.

Code (copy-paste safe)

```
def __init__(self, login, password, server, symbol=None, terminal_path=None):
    # Safely convert login to integer
    try:
        self.login = int(str(login).strip()) if login else 0

```

Method: MT5API._get_cached_terminal_path

```
def _get_cached_terminal_path(self)
    Get previously successful terminal path for faster connection
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Imports tempfile (lazy import inside the function).
2. Assigns `cache_file = os.path.join(tempfile.gettempdir(), 'mt5_terminal_cache.t....`
3. **try** block with 1 **except** clause.
4. **return** None.

Code (copy-paste safe)

```
def _get_cached_terminal_path(self):
    """Get previously successful terminal path for faster connection"""
    import tempfile
    cache_file = os.path.join(tempfile.gettempdir(), "mt5_terminal_cache.txt")

Verify symbol has live tick data available

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **for** attempt in range(max_retries): iterates.
2. Calls logging.error(...) for its side effect.
3. **return** False.

Code (copy-paste safe)

```
def _verify_symbol_tick_data(self, symbol, max_retries=3):
    """
    Verify symbol has live tick data available
    """
    for attempt in range(max_retries):
        try:
            tick = mt5.symbol_info_tick(symbol)
            if tick and tick.bid > 0 and tick.ask > 0:
                logging.info(f"[OK] Tick data verified for {symbol}: bid={tick.bid}, ask={tick.ask}")
                return True

            if attempt < max_retries - 1:
                logging.warning(
                    f"Tick data not available for {symbol} (attempt {attempt + 1}/{max_retries}), ret
                    time.sleep(0.1) # Brief delay before retry

        except Exception as e:
            logging.error(f"Error getting tick data for {symbol}: {e}")
            if attempt < max_retries - 1:
                time.sleep(0.1)

    logging.error(f"[ERROR] No tick data available for {symbol} after {max_retries} attempts")
    return False
```

Method: MT5API.is_autotrading_enabled

```
def is_autotrading_enabled(self)
```

Check if AutoTrading is enabled in MT5 using the existing connection Returns True if autotrading is enabled, False otherwise

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def is_autotrading_enabled(self):
```

```

"""
Check if AutoTrading is enabled in MT5 using the existing connection
Returns True if autotrading is enabled, False otherwise
"""
try:
    # Don't initialize a new connection - use the existing one
    if not self.connected:
        print("[ERROR] MT5 not connected - cannot check AutoTrading status")
        return False

    # Use the already connected MT5 instance to check terminal info
    term_info = mt5.terminal_info()
    if not term_info:
        print("[ERROR] Could not get terminal info from existing MT5 connection")
        return False

Method: MT5API._log_available_symbols

```
def _log_available_symbols(self, failed_symbol)
```

Log some available symbols for debugging

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with `append`, and clearer about intent: this is a transform, not a side-effecting loop.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to `sum`, `any`, `all`, or `max` where the intermediate list would be wasted.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

def _log_available_symbols(self, failed_symbol):
    """Log some available symbols for debugging"""

Comprehensive health check for MT5 connection and trading readiness Returns (is_healthy, error_message)

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def check_connection_health(self):
    """
    Comprehensive health check for MT5 connection and trading readiness
    Returns (is_healthy, error_message)
    """
    try:
        logging.info("■ Performing MT5 connection health check...")

        # 1. Check MT5 initialization
        if not mt5.initialize():
            return False, "MT5 not initialized"

        # 2. Check terminal connection
        terminal_info = mt5.terminal_info()
        if not terminal_info:
            return False, "Cannot get terminal info"

        if not terminal_info.connected:
            return False, "MT5 terminal not connected"

        if not terminal_info.trade_allowed:
            return False, "Trading not allowed in MT5 terminal"

        # 3. Check account access
        account_info = mt5.account_info()
        if not account_info:
            return False, "Cannot access account info"

        # 4. Check symbol availability (using configured symbol)
        if self.symbol:
            symbol_info = mt5.symbol_info(self.symbol)
            if not symbol_info:
                return False, f"Symbol {self.symbol} not found in MT5"

            if not symbol_info.visible:
                return False, f"Symbol {self.symbol} not visible in Market Watch"

        # 5. Check tick data availability
        tick = mt5.symbol_info_tick(self.symbol)
        if not tick or tick.bid <= 0 or tick.ask <= 0:
            return False, f"No live tick data for symbol {self.symbol}"

        logging.info("[OK] MT5 connection health check passed")
        return True, "All systems operational"

    except Exception as e:
        error_msg = f"Health check failed: {e}"
```

```
logging.error(f"[ERROR] {error_msg}")
return False, error_msg
```

Method: MT5API.attempt_reconnection

```
def attempt_reconnection(self, max_retries=3)
```

Attempt to reconnect to MT5 if connection is lost

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **for** attempt in range(max_retries): iterates.
2. Calls logging.error(...) for its side effect.
3. **return** False.

Code (copy-paste safe)

```
def attempt_reconnection(self, max_retries=3):
    """
    Attempt to reconnect to MT5 if connection is lost
    """
    for attempt in range(max_retries):
        try:
            logging.info(f"■ Attempting MT5 reconnection (attempt {attempt + 1}/{max_retries})...")

            # Shutdown current connection
            mt5.shutdown()

            # Wait a moment
            time.sleep(1)

            # Try to reconnect
            if self.connect():
                # Verify the reconnection worked
                is_healthy, health_msg = self.check_connection_health()
                if is_healthy:
                    logging.info("[OK] MT5 reconnection successful")
                    return True
                else:
                    logging.warning(f"Reconnection completed but health check failed: {health_msg}")
            else:
                logging.warning(f"Reconnection attempt {attempt + 1} failed")

        except Exception as e:
            logging.error(f"Error during reconnection attempt {attempt + 1}: {e}")

    logging.error(f"[ERROR] All {max_retries} reconnection attempts failed")
    return False
```

Method: MT5API._calculate_sl_tp_price

```
def _calculate_sl_tp_price(self, symbol, order_type, price, sl_points, tp_points)
```

Calculate SL and TP prices from points - NASDAQ automation always uses 1.0 point value

Why these Python concepts were used

- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `sl_price = None`.
2. Assigns `tp_price = None`.
3. Assigns `symbol_info = mt5.symbol_info(symbol)`.
4. **if not** `symbol_info`: branches conditionally.
5. Assigns `point = symbol_info.point`.
6. **if any**((`x in symbol.upper()` for `x in ['XAU', 'GOLD', 'GC']`)): branches conditionally (with an **else/elif** arm).
7. **if** `sl_points` and `float(sl_points) > 0`: branches conditionally.
8. **if** `tp_points` and `float(tp_points) > 0`: branches conditionally.
9. **return** (`sl_price`, `tp_price`).

Code (copy-paste safe)

```
def _calculate_sl_tp_price(self, symbol, order_type, price, sl_points, tp_points):
    """Calculate SL and TP prices from points - NASDAQ automation always uses 1.0 point value"""
    sl_price = None
    tp_price = None

    # Get symbol info for logging purposes
    symbol_info = mt5.symbol_info(symbol)

        f"TP calculation: {tp_points_float} points × {point_value} = {price_difference} price dif

return sl_price, tp_price

```

Method: MT5API.place_order

```
def place_order(self, symbol, order_type, volume=None, sl=None, tp=None, comment=None)
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression ([f(x) for x in xs]). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **raise** — Raises an exception explicitly. Either signals an invalid argument the caller should fix, or re-raises after logging.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. try block with 1 **except** clause.

Code (copy-paste safe)

```
def place_order(self, symbol, order_type, volume=None, sl=None, tp=None, comment=None):
```

```

    Close MT5 positions that don't have corresponding Tradovate trades
    Args: combine_comment_prefix:
    Comment prefix to identify trades from this combine (e.g., "Combine1_")
    Returns: int: Number of
    positions closed
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. try block with 1 except clause.

Code (copy-paste safe)

```
def close_orphaned_positions(self, combine_comment_prefix):
    """Close MT5 positions that don't have corresponding Tradovate trades

    Args:
        combine_comment_prefix: Comment prefix to identify trades from this combine (e.g., "Combine1

    Returns:
        int: Number of positions closed
    """
    try:

        logging.error(f"Error closing orphaned positions: {e}")
        return 0
```

Method: MT5API.close_trade

```
def close_trade(self, ticket, retries=3, delay=2)
```

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **for** attempt in range(retries): iterates.
2. Calls logging.error(...) for its side effect.
3. **return** not self.is_trade_open(ticket).

Code (copy-paste safe)

```
def close_trade(self, ticket, retries=3, delay=2):
    for attempt in range(retries):
        positions = mt5.positions_get(ticket=ticket)
        if not positions:

def close_orphaned_trades(self, expected_tradovate_trades)
```

Close MT5 trades that don't have corresponding Tradovate trades Args: *expected_tradovate_trades*: List of Tradovate trade symbols/IDs that should have MT5 counterparts Returns: List of closed MT5 trade tickets

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. try block with 1 except clause.

Code (copy-paste safe)

```
def close_orphaned_trades(self, expected_tradovate_trades):
    """Close MT5 trades that don't have corresponding Tradovate trades

    Args:
        expected_tradovate_trades: List of Tradovate trade symbols/IDs that should have MT5 counterpart

    Returns:
        List of closed MT5 trade tickets
    """

```

```
def get_installed_mt5_terminals()
```

Detect installed MetaTrader 5 terminals on Windows Returns a list of dictionaries with terminal info

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns terminals = [].
2. Calls logging.info(...) for its side effect.
3. Assigns username = os.getenv('USERNAME', "").
4. Assigns common_paths = ['C:\\Program Files\\MetaTrader 5', 'C:\\Program Files (x...
5. Assigns registry_paths = [(winreg.HKEY_LOCAL_MACHINE, 'SOFTWARE\\MetaQuotes\\Termi...
6. **for** (hkey, reg_path) in registry_paths: iterates.
7. **for** path in common_paths: iterates.

8. **try** block with 1 **except** clause.
9. Assigns `current_dir = os.path.dirname(os.path.abspath(__file__))`.
10. Assigns `parent_dir = os.path.dirname(current_dir)`.
11. Assigns `portable_paths = [os.path.join(parent_dir, 'MT5'), os.path.join(parent_dir....`
12. **for** `path in portable_paths`: iterates.
13. **try** block with 1 **except** clause.
14. Assigns `unique_terminals = []`.
15. ... and 13 more statement(s) in the body.

Step 7.2 — Build trader_companion/mt5_comment_parser.py

What to do. Create the file `trader_companion/mt5_comment_parser.py` in your project root and paste in the code shown in this step. The file is **869** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

What this file is for. Parses the structured comment field on MT5 orders so that trades can be linked back to the strategy that placed them.

trader_companion/mt5_comment_parser.py

869 loc · 5 classes · 4 functions · 5 imports

Parses the structured comment field on MT5 orders so that trades can be linked back to the strategy that placed them. It defines **5** classes and **4** module-level functions, across **869** lines. Module docstring: *MT5 Comment Parser Module*

Module docstring

MT5 Comment Parser Module Parses MT5 trade comments from TradeAccountConnector to extract account info and phase data.

Comment Format: {TradovateAccountNumber}{PhaseSuffix} Example: MFFUEVSTP326057008_CH1

Phase Suffix Reference: - _CH1-4: Challenge Trade 1-4 - _FD0: Funded Base (MFFU style) - _FD1-4: Funded/Payout 1-4 - _DD1-4: Double Dip 1-4 - _FA: Farming/Consistency - _FA_DDMMYY: Farming with date (e.g., _FA_210126 = Jan 21, 2026) - _UNK: Unknown phase

Python concepts demonstrated in this module

- Classes and objects
- Dataclasses
- Decorators
- Dunder methods
- Enums
- Exceptions
- f-strings
- Inheritance
- Properties
- Type hints

Imports — what each one is for

```
import re
```

Why imported. Regular expressions. Pattern matching, search, replace, and text extraction.

Used in this file. `re.IGNORECASE`, `re.Match`, `re.match`

Example. `re.search(r'\d{3}-\d{4}', text)` # returns a Match or None

Other common scenarios.

- `re.findall(pattern, text)` for every non-overlapping match
- `re.sub(pattern, repl, text)` to replace occurrences

- `re.compile(...)` to reuse a pattern (faster in a loop)
- Named groups: `r'(?P<year>\d{4})'` lets you do `m.group('year')`

```
from datetime import datetime
```

Why imported. Dates, times, durations. The fundamental temporal types: `date`, `time`, `datetime`, `timedelta`, `timezone`.

Used in this file. `datetime`

Example. `datetime.now() - timedelta(days=7)` # one week ago

Other common scenarios.

- `datetime.strptime(s, '%Y-%m-%d')` parses a string
- `datetime.strftime(fmt)` formats one
- `datetime.fromtimestamp(n)` converts a Unix epoch
- `datetime.utcnow()` for UTC (better: `datetime.now(timezone.utc)`)

```
from typing import Dict
from typing import List
from typing import Optional
from typing import Tuple
from typing import Any
```

Why imported. Type-hint primitives — generics, unions, `Optional`, `Callable`, `Protocol`, `TypeVar`, `TypedDict`.

Used in this file. `Any`, `Dict`, `List`, `Optional`, `Tuple`

Example. `def lookup(k: str) -> Optional[int]: ...`

Other common scenarios.

- `List[int]` / `Dict[str, Any]` / `Tuple[int, str]` (or bare `list[int]` on 3.9+)
- `Callable[[int, int], int]` for function signatures
- `Protocol` for structural typing (duck typing with checks)
- `TypeVar('T')` for generic functions and classes

```
from dataclasses import dataclass
from dataclasses import field
```

Why imported. `@dataclass` auto-generates `__init__` / `__repr__` / `__eq__` from annotated fields — boilerplate-free record types.

Used in this file. `dataclass`, `field`

Example. `@dataclass\nclass Trade:\n symbol: str\n volume: float = 0.1`

Other common scenarios.

- `field(default_factory=list)` for mutable defaults (NEVER use `= []`)
- `frozen=True` makes instances hashable and immutable
- `asdict(obj)` / `astuple(obj)` convert to dict or tuple
- `@dataclass(slots=True)` saves memory (3.10+)

```
from enum import Enum
```

Why imported. Enumerated constants. Replaces magic strings/numbers with a type that has both a name and a value.

Used in this file. Enum

Example. `class Phase(Enum):\n CHALLENGE = 'challenge'\n FUNDED = 'funded'`

Other common scenarios.

- `IntEnum` for an enum that compares equal to its int value
- `auto()` lets you skip explicit values
- `Phase['CHALLENGE']` looks up by name; `Phase('challenge')` by value

Classes

```
class Phase(Enum)
```

Trading phase types.

```
CHALLENGE = 'CH'\nFUNDED = 'FD'\nDOUBLE_DIP = 'DD'\nFARMING = 'FA'\nUNKNOWN = 'UNK'\nLEGACY = 'LEGACY'
```

Code (copy-paste safe)

```
class Phase(Enum):\n    """Trading phase types."""\n    CHALLENGE = "CH"          # Challenge trades\n    FUNDED = "FD"             # Funded/Payout trades\n    DOUBLE_DIP = "DD"         # Double Dip trades\n    FARMING = "FA"            # Farming/Consistency phase\n    UNKNOWN = "UNK"           # Unknown phase\n    LEGACY = "LEGACY"
```

```
@dataclass
```

```
class ParsedComment
```

Parsed MT5 comment data.

```
account_number: Optional[str] = None\nphase: Optional[Phase] = None\nphase_code: Optional[str] = None\ntrade_number: Optional[int] = None\nfarming_date: Optional[datetime] = None\nraw_comment: str = ''\nis_valid: bool = False
```

Code (copy-paste safe)

```
class ParsedComment:\n    """Parsed MT5 comment data."""\n    account_number: Optional[str] = None\n    phase: Optional[Phase] = None
```

```

phase_code: Optional[str] = None # Raw phase code (CH, FD, DD, FA, UNK)
trade_number: Optional[int] = None
farming_date: Optional[datetime] = None
raw_comment: str = ""
is_valid: bool = False

def __str__(self):
    if not self.is_valid:
        return f"Invalid: {self.raw_comment}"

    date_str = f" ({self.farming_date.strftime('%d/%m/%y')})" if self.farming_date else ""
    trade_str = f" Trade #{self.trade_number}" if self.trade_number else ""
    return f"{self.account_number} | {self.phase.name}{trade_str}{date_str}"

def to_dict(self) -> Dict:
    """Convert to dictionary."""
    return {
        "account_number": self.account_number,
        "phase": self.phase.value if self.phase else None,
        "phase_name": self.phase.name if self.phase else None,
        "phase_code": self.phase_code,
        "trade_number": self.trade_number,
        "farming_date": self.farming_date.isoformat() if self.farming_date else None,
        "raw_comment": self.raw_comment,
        "is_valid": self.is_valid
    }

```

Method: ParsedComment.__str__

```
def __str__(self)
```

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.
- **__str__** — Defines **__str__** so the instance has a useful string representation in logs, the REPL, and error messages.

Step by step (top-level body)

1. **if** not self.is_valid: branches conditionally.
2. Assigns date_str = f" ({self.farming_date.strftime('%d/%m/%y')})" if self.fa....
3. Assigns trade_str = f" Trade #{self.trade_number}" if self.trade_number else "".
4. **return** f'{self.account_number} | {self.phase.name}{trade_str}{date_str}'.

Code (copy-paste safe)

```

def __str__(self):
    if not self.is_valid:
        return f"Invalid: {self.raw_comment}"

    date_str = f" ({self.farming_date.strftime('%d/%m/%y')})" if self.farming_date else ""
    trade_str = f" Trade #{self.trade_number}" if self.trade_number else ""
    return f"{self.account_number} | {self.phase.name}{trade_str}{date_str}"

```

Method: ParsedComment.to_dict

```
def to_dict(self) -> Dict
```

Convert to dictionary.

Why these Python concepts were used

- **return type annotation** — Annotated return type -> Dict. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **return** {'account_number': self.account_number, 'phase': self.phase.value i....

Code (copy-paste safe)

```
def to_dict(self) -> Dict:
    """Convert to dictionary."""
    return {
        "account_number": self.account_number,
        "phase": self.phase.value if self.phase else None,
        "phase_name": self.phase.name if self.phase else None,
        "phase_code": self.phase_code,
        "trade_number": self.trade_number,
        "farming_date": self.farming_date.isoformat() if self.farming_date else None,
        "raw_comment": self.raw_comment,
        "is_valid": self.is_valid
    }
```

@dataclass

class AggregatedTrade

    }

```

Method: AggregatedTrade.net_profit

```

@property
def net_profit(self) -> float
    Net profit including all costs.

```

Why these Python concepts were used

- **@property** — Wrapped in **@property** so callers access the value with attribute syntax (`obj.x`) instead of a method call. Lets the implementation compute or validate the value lazily without changing the call site.
- **return type annotation** — Annotated return type `-> float`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. `return self.total_profit + self.total_commission + self.total_swap + self.....`

Code (copy-paste safe)

```
def net_profit(self) -> float:
    """Net profit including all costs."""
    return self.total_profit + self.total_commission + self.total_swap + self.total_fee
```

Method: `AggregatedTrade.account_signature`

```
@property
def account_signature(self) -> str

    Get first4+last4 account signature for matching.
```

Why these Python concepts were used

- **@property** — Wrapped in **@property** so callers access the value with attribute syntax (`obj.x`) instead of a method call. Lets the implementation compute or validate the value lazily without changing the call site.
- **return type annotation** — Annotated return type `-> str`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. `return get_account_signature(self.account_number).`

Code (copy-paste safe)

```
def account_signature(self) -> str:
    """Get first4+last4 account signature for matching."""
    return get_account_signature(self.account_number)
```

Method: `AggregatedTrade.get_key`

```
def get_key(self) -> str

    Get unique key for this aggregation.
```

Why these Python concepts were used

- **return type annotation** — Annotated return type `-> str`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns `date_suffix = f"_{self.farming_date.strftime('%d%m%y')}"` if `self.farmin...`
2. Assigns `trade_suffix = str(self.trade_number)` if `self.trade_number` else `"`.
3. **return** `f'{self.account_number}_{self.phase_code}{trade_suffix}{date_suffix}'`.

Code (copy-paste safe)

```
def get_key(self) -> str:
    """Get unique key for this aggregation."""
    date_suffix = f"_{self.farming_date.strftime('%d%m%y')}" if self.farming_date else ""
    trade_suffix = str(self.trade_number) if self.trade_number else ""
    return f'{self.account_number}_{self.phase_code}{trade_suffix}{date_suffix}'
```

Method: AggregatedTrade.to_dict

```
def to_dict(self) -> Dict
```

Convert to dictionary.

Why these Python concepts were used

- **return type annotation** — Annotated return type -> Dict. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **ternary expression** — Uses `x` if `cond` else `y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **return** `{'account_number': self.account_number, 'phase': self.phase.value, ...`

Code (copy-paste safe)

```
def to_dict(self) -> Dict:
    """Convert to dictionary."""

        (r'^(.+?)_UNK$', self._parse_unknown_phase),
        # Legacy Combine format
        (r'^Combine(\d+)_(.*)$', self._parse_legacy_combine),
    ]
```

Method: MT5CommentParser.parse

```
def parse(self, comment: str) -> ParsedComment
```

Parse an MT5 trade comment. Args: comment: The MT5 order comment string Returns: ParsedComment object with extracted data

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., comment: str). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.

- **return type annotation** — Annotated return type -> `ParsedComment`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. Assigns `result = ParsedComment(raw_comment=comment or "")`.
2. **if** not comment: branches conditionally.
3. Assigns `comment = comment.strip()`.
4. **for** (pattern, handler) in `self.patterns`: iterates.
5. **if** comment and (not `comment.startswith('Combine')`): branches conditionally.
6. **return** result.

Code (copy-paste safe)

```
def parse(self, comment: str) -> ParsedComment:
    """
    Parse an MT5 trade comment.

    Args:
        comment: The MT5 order comment string

    Returns:
        ParsedComment object with extracted data
    """
    result = ParsedComment(raw_comment=comment or "")

    if not comment:
        return result

    comment = comment.strip()

    # Try each pattern
    for pattern, handler in self.patterns:
        match = re.match(pattern, comment, re.IGNORECASE)
        if match:
            return handler(match, comment)

    # No pattern matched - check if it's just an account number
    # (comment without phase suffix)
    if comment and not comment.startswith("Combine"):
        result.account_number = comment
        result.is_valid = False # Mark as not fully valid without phase

    return result
```

Method: `MT5CommentParser._parse_numbered_phase`

```
def _parse_numbered_phase(self, match: re.Match, comment: str) -> ParsedComment
    Parse numbered phases: CH, FD, DD with trade number.
```

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `match: re.Match`, `comment: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.

- **return type annotation** — Annotated return type -> `ParsedComment`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. Assigns `account = match.group(1)`.
2. Assigns `phase_code = match.group(2).upper()`.
3. Assigns `trade_num = int(match.group(3))`.
4. Assigns `phase_map = {'CH': Phase.CHALLENGE, 'FD': Phase.FUNDED, 'DD': Phase.D...`
5. **return** `ParsedComment(account_number=account, phase=phase_map.get(phase_cod....`

Code (copy-paste safe)

```
def _parse_numbered_phase(self, match: re.Match, comment: str) -> ParsedComment:
    """Parse numbered phases: CH, FD, DD with trade number."""
    account = match.group(1)
    phase_code = match.group(2).upper()
    trade_num = int(match.group(3))

    phase_map = {
        "CH": Phase.CHALLENGE,

```
def _parse_farming_with_date(self, match: re.Match, comment: str) -> ParsedComment
    Parse farming phase with date: _FA_DDMMYY.
```

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `match: re.Match, comment: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type -> `ParsedComment`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

Step by step (top-level body)

1. Assigns `account = match.group(1)`.

2. Assigns `date_str = match.group(2)`.
3. Assigns `farming_date = None`.
4. **try** block with 1 **except** clause.
5. **return** `ParsedComment(account_number=account, phase=Phase.FARMING, phase_co....`

Code (copy-paste safe)

```
def _parse_farming_with_date(self, match: re.Match, comment: str) -> ParsedComment:
    """Parse farming phase with date: _FA_DDMMYY."""
    account = match.group(1)
    date_str = match.group(2) # DDMMYY format

    farming_date = None
    try:
        farming_date = datetime.strptime(date_str, "%d%m%y")
    except ValueError:
        pass

    return ParsedComment(
        account_number=account,
        phase=Phase.FARMING,
        phase_code="FA",
        farming_date=farming_date,
        raw_comment=comment,
        is_valid=True
    )
```

Method: `MT5CommentParser._parse_simple_farming`

```
def _parse_simple_farming(self, match: re.Match, comment: str) -> ParsedComment
    Parse simple farming phase: _FA.
```

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `match: re.Match, comment: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> ParsedComment`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. **return** `ParsedComment(account_number=match.group(1), phase=Phase.FARMING, p....`

Code (copy-paste safe)

```
def _parse_simple_farming(self, match: re.Match, comment: str) -> ParsedComment:

        account_number=match.group(1),
        phase=Phase.UNKNOWN,
        phase_code="UNK",
        raw_comment=comment,
        is_valid=True
    )
```

Method: MT5CommentParser._parse_legacy_combine

```
def _parse_legacy_combine(self, match: re.Match, comment: str) -> ParsedComment
    Parse legacy Combine format: Combine{N}_.
```

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., match: re.Match, comment: str). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type -> ParsedComment. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. Assigns combinenum = match.group(1).
2. Assigns rest = match.group(2).
3. **return** ParsedComment(account_number=rest, phase=Phase.CHALLENGE, phase_cod....

Code (copy-paste safe)

```
def _parse_legacy_combine(self, match: re.Match, comment: str) -> ParsedComment:
    """Parse legacy Combine format: Combine{N}_."""
    combinenum = match.group(1)
    rest = match.group(2)
    # Usually Combine1_Account
```

```

    return ParsedComment(
        account_number=rest,
        phase=Phase.CHALLENGE,
        phase_code="CH",
        trade_number=int(combinenum),
        raw_comment=comment,
        is_valid=True
    )

```

Method: MT5CommentParser.get_phase_meaning

```
def get_phase_meaning(self, phase_code: str, prop_firm: str='MFFU') -> str
```

*Get human-readable meaning for a phase code. Args: phase_code: Phase code (CH, FD, DD, FA)
prop_firm: Prop firm name for context-specific meaning Returns: Description of the phase*

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `phase_code: str`, `prop_firm: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> str`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `firm_meanings = self.PHASE_MEANINGS.get(prop_firm, self.PHASE_MEANINGS['M....`
2. **return** `firm_meanings.get(phase_code, f'Unknown phase: {phase_code}')`.

Code (copy-paste safe)

```

def get_phase_meaning(self, phase_code: str, prop_firm: str = "MFFU") -> str:
    """
    Get human-readable meaning for a phase code.

    Args:
        phase_code: Phase code (CH, FD, DD, FA)
        prop_firm: Prop firm name for context-specific meaning

    Returns:
        Description of the phase
    """
    firm_meanings = self.PHASE_MEANINGS.get(prop_firm, self.PHASE_MEANINGS["MFFU"])
    return firm_meanings.get(phase_code, f"Unknown phase: {phase_code}")

```

```

return result

```

Method: MT5DealAggregator.__init__

```
def __init__(self)

    Initialize the aggregator.
```

Why these Python concepts were used

- **__init__** — The constructor. Runs after Python has allocated the instance; assigns starting attribute values to self.

Step by step (top-level body)

1. Assigns self.parser = MT5CommentParser().
2. Declares self.aggregations: Dict[str, AggregatedTrade] = {}.
3. Declares self.unmatched_deals: List[Dict] = [].
4. Declares self.parse_log: List[str] = [].

Code (copy-paste safe)

```
def __init__(self):
    """Initialize the aggregator."""
    self.parser = MT5CommentParser()
    self.aggregations: Dict[str, AggregatedTrade] = {}
    self.unmatched_deals: List[Dict] = []
    self.parse_log: List[str] = []

```

Method: MT5DealAggregator.reset

```
def reset(self)

    Reset aggregation state.
```

Step by step (top-level body)

1. Assigns self.aggregations = {}.
2. Assigns self.unmatched_deals = [].
3. Assigns self.parse_log = [].

Code (copy-paste safe)

```
def reset(self):
    """Reset aggregation state."""
    self.aggregations = {}
    self.unmatched_deals = []
    self.parse_log = []

```

Method: MT5DealAggregator.add_deal

```
def add_deal(self, deal: Dict) -> Optional[str]
```

Add a single deal to the aggregation. Args: deal: MT5 deal dictionary with fields like: - comment: Order comment - profit: Deal profit - commission: Commission - swap: Swap charges - fee: Additional fees - type: Deal type (BUY, SELL, BALANCE, etc.) - entry: Entry type (IN, OUT, INOUT) Returns: Aggregation key if matched, None if unmatched

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `deal: Dict`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> Optional[str]`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.

Step by step (top-level body)

1. Assigns `deal_type = str(deal.get('type', '')).upper()`.
2. **if** `deal_type` in `['BALANCE', 'CREDIT', '2', '3', 'CHARGE', 'CORRECTION']`: branches conditionally.
3. Assigns `comment = deal.get('comment', '')`.
4. Assigns `parsed = self.parser.parse(comment)`.
5. **if** `not parsed.is_valid` or `not parsed.account_number`: branches conditionally.
6. Assigns `deal_time_str = deal.get('time', '')`.
7. Assigns `deal_date = None`.
8. **try** block with 1 **except** clause.
9. **if** `not parsed.farming_date` and `deal_date`: branches conditionally.
10. Assigns `key = self._build_key(parsed)`.
11. **if** `key` not in `self.aggregations`: branches conditionally.
12. Assigns `agg = self.aggregations[key]`.
13. Updates `agg.total_profit` in place (Add).
14. Updates `agg.total_commission` in place (Add).
15. ... and 7 more statement(s) in the body.

Code (copy-paste safe)

        account = agg.account_number
        if account not in summary:
            summary[account] = {"phases": {}, "total_net_profit": 0.0}

        phase_key = f"{agg.phase_code}{agg.trade_number or ''}"
        summary[account]["phases"][phase_key] = agg.net_profit
        summary[account]["total_net_profit"] += agg.net_profit

    return summary
```

Method: MT5DealAggregator.to_dashboard_format

```
def to_dashboard_format(self) -> List[Dict]
```

Convert aggregations to dashboard-compatible format. Returns list of dicts with:

- *account_number*: Account identifier
- *phase*: Phase code (CH, FD, DD, FA)
- *trade_number*: Trade number (1-4) or None
- *farming_date*: Date if farming phase
- *net_profit*: Total net profit for this combination
- *deal_count*: Number of deals

Why these Python concepts were used

- **return type annotation** — Annotated return type -> List[Dict]. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. Assigns result = [].
2. for (key, agg) in self.aggregations.items(): iterates.
3. return result.

Code (copy-paste safe)

```
def to_dashboard_format(self) -> List[Dict]:
    """
    Convert aggregations to dashboard-compatible format.

    Returns list of dicts with:
```

```

- account_number: Account identifier
- phase: Phase code (CH, FD, DD, FA)
- trade_number: Trade number (1-4) or None
- farming_date: Date if farming phase
- net_profit: Total net profit for this combination
- deal_count: Number of deals
"""
result = []
for key, agg in self.aggregations.items():
    result.append(agg.to_dict())
return result

```

Functions

```
def get_account_signature(account: str) -> str
```

Generate account signature from first 4 + last 4/5 characters. Used for matching truncated account numbers. Handles truncated format with '...' like: FNFT...59574 Examples: MFFUEVSTP326057008 -> mffu7008 (full account) FNFT...59574 -> fnft59574 (truncated - use last 5) MFFU7008 -> mffu7008 (short account)

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `account: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> str`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **if** not `account`: branches conditionally.
2. Assigns `account = account.strip()`.
3. **if** `'...'` in `account`: branches conditionally.
4. **if** `len(account) <= 8`: branches conditionally.
5. **return** `(account[:4] + account[-4:]).lower()`.

Code (copy-paste safe)

```

def get_account_signature(account: str) -> str:
    """
    Generate account signature from first 4 + last 4/5 characters.
    Used for matching truncated account numbers.

    Handles truncated format with '...' like: FNFT...59574

    Examples:
        MFFUEVSTP326057008 -> mffu7008 (full account)
        FNFT...59574 -> fnft59574 (truncated - use last 5)
        MFFU7008 -> mffu7008 (short account)
    """

```

```

if not account:
    return ""
account = account.strip()

# Handle truncated format: PREFIX...SUFFIX
if '...' in account:
    parts = account.split('...')
    if len(parts) == 2:
        prefix = parts[0][:4] if len(parts[0]) >= 4 else parts[0]
        suffix = parts[1] # Keep full suffix (usually 5 digits)
        return (prefix + suffix).lower()

# Standard format: first 4 + last 4
if len(account) <= 8:
    return account.lower()
return (account[:4] + account[-4:]).lower()

```

```
def parse_mt5_comment(comment: str) -> Dict
```

*Convenience function to parse a single MT5 comment. Args: comment: MT5 order comment string
Returns: Dictionary with parsed data: - account_number: Tradovate account number - phase: Phase code (CH, FD, DD, FA) - trade_number: Trade number (1-4) or None for farming - farming_date: Date if farming phase with date suffix - is_valid: Whether the comment was successfully parsed*

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., comment: str). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type -> Dict. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. Assigns parser = MT5CommentParser().
2. Assigns result = parser.parse(comment).
3. **return** result.to_dict().

Code (copy-paste safe)

```

def parse_mt5_comment(comment: str) -> Dict:
    """
    Convenience function to parse a single MT5 comment.

    Args:
        comment: MT5 order comment string

    Returns:
        Dictionary with parsed data:
        - account_number: Tradovate account number
        - phase: Phase code (CH, FD, DD, FA)
        - trade_number: Trade number (1-4) or None for farming
        - farming_date: Date if farming phase with date suffix
        - is_valid: Whether the comment was successfully parsed
    """
    parser = MT5CommentParser()

```

```

result = parser.parse(comment)
return result.to_dict()

```

```

def aggregate_deals_by_comment(deals: List[Dict]) -> Tuple[List[Dict], List[Dict], List[str]]

```

Convenience function to aggregate deals by parsed comments. Args: deals: List of MT5 deal dictionaries Returns: Tuple of (aggregated_data, unmatched_deals, log_messages)

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., deals: List[Dict]). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type -> Tuple[List[Dict], List[Dict], List[str]]. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. Assigns aggregator = MT5DealAggregator().
2. Calls aggregator.process_deals(...) for its side effect.
3. **return** (aggregator.to_dashboard_format(), aggregator.unmatched_deals, aggr....

Code (copy-paste safe)

```

def aggregate_deals_by_comment(deals: List[Dict]) -> Tuple[List[Dict], List[Dict], List[str]]:
    """
    Convenience function to aggregate deals by parsed comments.

    Args:
        deals: List of MT5 deal dictionaries

    Returns:
        Tuple of (aggregated_data, unmatched_deals, log_messages)
    """
    aggregator = MT5DealAggregator()
    aggregator.process_deals(deals)

    return (
        aggregator.to_dashboard_format(),
        aggregator.unmatched_deals,
        aggregator.parse_log
    )

```

```

def aggregate_deals_by_position(deals: List[Any]) -> Tuple[List[Dict], List[Dict], List[str]]

```

Aggregate deals by position_id first, then by comment/phase. Also handles "Farming" cluster logic: - If Phase is FARMING (FA) and no date in comment, uses Trade Date (Time). Args: deals: List of MT5 deal objects or dicts Returns: Tuple of (aggregated_data, unmatched_positions, log_messages)

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., deals: List[Any]). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.

- **return type annotation** — Annotated return type -> Tuple[List[Dict], List[Dict], List[str]]. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns parser = MT5CommentParser().
2. Assigns log_messages = [].
3. Assigns positions = {}.
4. **for** deal in deals: iterates.
5. Calls log_messages.append(...) for its side effect.
6. Assigns position_data = [].
7. Assigns unmatched = [].
8. **for** (pid, deal_list) in positions.items(): iterates.
9. Calls log_messages.append(...) for its side effect.
10. Assigns aggregated = {}.
11. **for** pos in position_data: iterates.
12. **for** (key, agg) in aggregated.items(): iterates.
13. **return** (list(aggregated.values()), unmatched, log_messages).

Code (copy-paste safe)

```
def aggregate_deals_by_position(deals: List[Any]) -> Tuple[List[Dict], List[Dict], List[str]]:
    """
    Aggregate deals by position_id first, then by comment/phase.

    Also handles "Farming" cluster logic:

```

Step 7.3 — Build

trader_companion/trade_limit_manager.py

What to do. Create the file `trader_companion/trade_limit_manager.py` in your project root and paste in the code shown in this step. The file is **388** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

What this file is for. Enforces per-account daily loss and position-size limits. The guardrail that prevents one bad day from killing a funded account.

trader_companion/trade_limit_manager.py

388 loc · 2 classes · 4 functions · 5 imports

Enforces per-account daily loss and position-size limits. The guardrail that prevents one bad day from killing a funded account. It defines **2** classes and **4** module-level functions, across **388** lines. Module docstring: *Trade Limit Manager for Combine-Based Trading*

Module docstring

Trade Limit Manager for Combine-Based Trading Manages trade limits based on the number of combines purchased and active MT5 trades

Python concepts demonstrated in this module

• Classes and objects • Comprehensions • Context managers (with-statements) • Dunder methods • Exceptions • f-strings • Lambdas • Type hints

Imports — what each one is for

```
import sys
```

Why imported. Access to the running interpreter — argv, stdin/stdout, exit codes, the import search path, and the platform name.

Used in this file. sys.path, sys.path.append

Example. sys.exit(1) # terminate the process with a non-zero status

Other common scenarios.

- sys.argv[1:] reads the command-line arguments
- sys.path.insert(0, 'extra') prepends to the import search path
- sys.stderr.write(msg) writes to standard error
- sys.platform tells you 'win32', 'linux', or 'darwin'
- sys.modules is the global cache of already-imported modules

```
import os
```

Why imported. Operating-system interface. Path manipulation, environment variables, working-directory operations, exit codes, and thin wrappers around POSIX/Windows syscalls.

Used in this file. os.path, os.path.dirname, os.path.exists

Example. os.path.join(root, 'subdir', 'file.txt') # joins with the OS-correct separator

Other common scenarios.

- os.environ.get('API_KEY') to read environment variables
- os.makedirs(path, exist_ok=True) to create nested directories
- os.listdir(path) to list a directory's contents
- os.remove(path) / os.rename(src, dst) to delete or move a file
- os.getcwd() / os.chdir(path) to inspect or change the working dir

```
import logging
```

Why imported. Structured, levelled logging. Replaces print() with filterable, formattable output that can route to files, stderr, syslog, or HTTP endpoints.

Used in this file. logging.error, logging.info, logging.warning

Example. `logging.getLogger(__name__).info('connected to %s', host)`

Other common scenarios.

- `.debug()` / `.info()` / `.warning()` / `.error()` / `.exception()`
- `logger.exception()` captures the current traceback automatically
- `logging.basicConfig(level=logging.INFO)` for quick setup
- Handlers and Formatters route logs to files / streams / syslog

```
import time
```

Why imported. Timestamps and sleep. Lower-level than `datetime` — works in Unix-epoch seconds.

Used in this file. `time.time`

Example. `time.sleep(1.5)` # pause this thread for 1.5 seconds

Other common scenarios.

- `time.time()` returns seconds since the epoch
- `time.monotonic()` for measuring elapsed time (never goes backward)
- `time.perf_counter()` for high-precision benchmarking
- `time.strftime` / `time.strptime` mirror the `datetime` versions

```
from typing import Dict
from typing import List
from typing import Optional
from typing import Tuple
```

Why imported. Type-hint primitives — generics, unions, `Optional`, `Callable`, `Protocol`, `TypeVar`, `TypedDict`.

Used in this file. `Dict`, `Tuple`

Example. `def lookup(k: str) -> Optional[int]: ...`

Other common scenarios.

- `List[int]` / `Dict[str, Any]` / `Tuple[int, str]` (or bare `list[int]`+ on 3.9+)
- `Callable[[int, int], int]` for function signatures
- `Protocol` for structural typing (duck typing with checks)
- `TypeVar('T')` for generic functions and classes

Classes

```
class TradeLimit
```

Represents trade limit information for a combine

Code (copy-paste safe)

```
class TradeLimit:
    """Represents trade limit information for a combine"""
    def __init__(self, combine_id: str, max_trades: int, account_name: str = ""):
        self.combine_id = combine_id
        self.max_trades = max_trades
```

```

        self.account_name = account_name
        self.active_trades = 0
        self.last_check = 0

    def can_place_trade(self) -> bool:
        """Check if a new trade can be placed"""
        return self.active_trades < self.max_trades

    def remaining_trades(self) -> int:
        """Get number of remaining trade slots"""
        return max(0, self.max_trades - self.active_trades)

```

Method: TradeLimit.__init__

```
def __init__(self, combine_id: str, max_trades: int, account_name: str='')
```

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `combine_id: str`, `max_trades: int`, `account_name: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **__init__** — The constructor. Runs after Python has allocated the instance; assigns starting attribute values to `self`.

Step by step (top-level body)

1. Assigns `self.combine_id = combine_id`.
2. Assigns `self.max_trades = max_trades`.
3. Assigns `self.account_name = account_name`.
4. Assigns `self.active_trades = 0`.
5. Assigns `self.last_check = 0`.

Code (copy-paste safe)

```

def __init__(self, combine_id: str, max_trades: int, account_name: str = ""):
    self.combine_id = combine_id
    self.max_trades = max_trades
    self.account_name = account_name

    self.last_check = 0

```

Method: TradeLimit.can_place_trade

```
def can_place_trade(self) -> bool
```

Check if a new trade can be placed

Why these Python concepts were used

- **return type annotation** — Annotated return type `-> bool`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. **return** self.active_trades < self.max_trades.

Code (copy-paste safe)

```
def can_place_trade(self) -> bool:
    """Check if a new trade can be placed"""
    return self.active_trades < self.max_trades
```

Method: TradeLimit.remaining_trades

```
def remaining_trades(self) -> int
```

Get number of remaining trade slots

Why these Python concepts were used

- **return type annotation** — Annotated return type -> int. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. **return** max(0, self.max_trades - self.active_trades).

Code (copy-paste safe)

```
def remaining_trades(self) -> int:
    """Get number of remaining trade slots"""
    return max(0, self.max_trades - self.active_trades)
```

```
class TradeLimitManager
```

Manages trade limits across multiple combines

```

Method: TradeLimitManager.__init__

```
def __init__(self, max_trades: int=5)
```

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `max_trades: int`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **__init__** — The constructor. Runs after Python has allocated the instance; assigns starting attribute values to self.

Step by step (top-level body)

1. Declares `self.combines: Dict[str, TradeLimit] = {}`.
2. Assigns `self.mt5 = None`.
3. Assigns `self.last_mt5_check = 0`.
4. Assigns `self.check_interval = 5`.
5. Assigns `self.max_trades = max_trades`.
6. Assigns `self.default_combines = {'5_combine': 5, '10_combine': 10, '15_combine': 15, '20_....`
7. Calls `self.add_combine(...)` for its side effect.
8. Calls `self._initialize_mt5(...)` for its side effect.

Code (copy-paste safe)

```

def __init__(self, max_trades: int = 5):
    self.combines: Dict[str, TradeLimit] = {}
    self.mt5 = None
    self.last_mt5_check = 0
    self.check_interval = 5 # Check MT5 every 5 seconds
    self.max_trades = max_trades # Store the max trades limit

```

```

# Default combine configurations
self.default_combines = {
    "5_combine": 5,
    "10_combine": 10,
    "15_combine": 15,
    "20_combine": 20
}

# Add a default combine with the specified max trades
self.add_combine("default", max_trades, "Default Account")

self._initialize_mt5()

```

Method: TradeLimitManager._initialize_mt5

```
def _initialize_mt5(self)
```

Initialize MT5 connection - MT5 API will be set by the main application

Step by step (top-level body)

1. Assigns self.mt5 = None.

Code (copy-paste safe)

```

def _initialize_mt5(self):
    """Initialize MT5 connection - MT5 API will be set by the main application"""
    # MT5 API instance will be set by the application through set_mt5_api() method
    self.mt5 = None

```

Method: TradeLimitManager.add_combine

```
def add_combine(self, combine_id: str, max_trades: int, account_name: str='') -> bool
```

Add a new combine with specified trade limit

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., combine_id: str, max_trades: int, account_name: str). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type -> bool. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. try block with 1 **except** clause.

Code (copy-paste safe)

```
def add_combine(self, combine_id: str, max_trades: int, account_name: str = "") -> bool:
```

```

        """Add a new combine with specified trade limit"""
        try:
            self.combines[combine_id] = TradeLimit(combine_id, max_trades, account_name)
            logging.info(f"■ Added combine {combine_id} with {max_trades} trade limit")
            return True
        except Exception as e:
            logging.error(f"■ Failed to add combine {combine_id}: {e}")
            return False

```

Method: TradeLimitManager.remove_combine

```
def remove_combine(self, combine_id: str) -> bool
```

Remove a combine

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `combine_id: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> bool`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

def remove_combine(self, combine_id: str) -> bool:
    """Remove a combine"""
    try:
        if combine_id in self.combines:
            del self.combines[combine_id]
            logging.info(f"■ Removed combine {combine_id}")
            return True
        else:
            logging.warning(f"■ Combine {combine_id} not found")
            return False
    except Exception as e:
        logging.error(f"■ Failed to remove combine {combine_id}: {e}")
        return False

```

Method: TradeLimitManager.set_mt5_api

```
def set_mt5_api(self, mt5_api)
```

Set the MT5 API instance from the main application

Step by step (top-level body)

1. Assigns `self.mt5 = mt5_api`.
2. `if mt5_api`: branches conditionally.

Code (copy-paste safe)

```
def set_mt5_api(self, mt5_api):
    """Set the MT5 API instance from the main application"""
    self.mt5 = mt5_api
    if mt5_api:
        logging.info("■ MT5 API set for trade limit checking")
```

Method: `TradeLimitManager.get_active_trades_from_mt5`

```
def get_active_trades_from_mt5(self) -> int

    Get number of active trades from MT5 terminal
```

Why these Python concepts were used

- **return type annotation** — Annotated return type `-> int`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **try/except** — Wraps part of the body in `try/except`. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. `if not self.mt5`: branches conditionally.
2. `try` block with 1 `except` clause.

Code (copy-paste safe)

```
def get_active_trades_from_mt5(self) -> int:
    """Get number of active trades from MT5 terminal"""
    if not self.mt5:
        return 0

    try:
        # Initialize MT5 if not already done
        if not self.mt5.initialize():
            logging.error("■ Failed to initialize MT5 for trade checking")
            return 0

        # Get all open positions
        positions = self.mt5.positions_get()
        if positions is None:
            positions = []

        active_count = len(positions)
        logging.info(f"■ MT5 active trades: {active_count}")

        # Get detailed position info
```

```

        if active_count > 0:
            logging.info("■ Active positions:")
            for i, pos in enumerate(positions):
                symbol = pos.symbol
                volume = pos.volume
                position_type = "BUY" if pos.type == 0 else "SELL"
                profit = pos.profit
                logging.info(f"    {i+1}. {symbol} {position_type} {volume} lots (P&L: {profit:.2f})")

        # Shutdown MT5 connection
        self.mt5.shutdown()

        return active_count

    except Exception as e:
        logging.error(f"■ Error checking MT5 active trades: {e}")
        try:
            self.mt5.shutdown()
        except:
            pass
        return 0

```

Method: TradeLimitManager.update_active_trades_all_combines

```
def update_active_trades_all_combines(self) -> bool
```

Update active trade counts for all combines from MT5

Why these Python concepts were used

- **return type annotation** — Annotated return type -> bool. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `current_time = time.time()`.
2. `if current_time - self.last_mt5_check < self.check_interval`: branches conditionally.
3. `try` block with 1 `except` clause.

Code (copy-paste safe)

```

def update_active_trades_all_combines(self) -> bool:
    """Update active trade counts for all combines from MT5"""
    current_time = time.time()

    # Only check if enough time has passed
    if current_time - self.last_mt5_check < self.check_interval:
        return True

    try:
        total_active = self.get_active_trades_from_mt5()

```

```

        # Update all combines with current active trade count
        for combine_id, combine in self.combines.items():
            combine.active_trades = total_active
            combine.last_check = current_time
            logging.info(f"■ {combine_id}: {combine.active_trades}/{combine.max_trades} trades active")

        self.last_mt5_check = current_time
        return True

    except Exception as e:
        logging.error(f"■ Failed to update active trades: {e}")
        return False

```

Method: TradeLimitManager.can_place_trade

```
def can_place_trade(self, combine_id: str=None) -> Tuple[bool, str]
```

Check if a new trade can be placed Returns: (can_place, reason)

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `combine_id: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> Tuple[bool, str]`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to `sum`, `any`, `all`, or `max` where the intermediate list would be wasted.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Calls `self.update_active_trades_all_combines(...)` for its side effect.
2. `if not combine_id:` branches conditionally.
3. `if combine_id in self.combines:` branches conditionally (with an **else/elif** arm).

Code (copy-paste safe)

```

def can_place_trade(self, combine_id: str = None) -> Tuple[bool, str]:
    """
    Check if a new trade can be placed
    Returns: (can_place, reason)
    """
    # Update active trades from MT5
    self.update_active_trades_all_combines()

    # Use default combine if none specified
    if not combine_id:
        combine_id = "default"

    if combine_id in self.combines:
        # Check specific combine
        combine = self.combines[combine_id]

```

```

    else:
        active_info = ", ".join(f"{cid}({c.active_trades}/{c.max_trades})"
                                for cid, c in self.combines.items())
        error_message = f"■ All trade limits reached. Active: {active_info}"

        # Show popup alert for all limits exceeded
        popup_message = (f"■ ALL TRADE LIMITS EXCEEDED ■\n\n"
                        f"All your combines have reached their maximum trades:\n"
                        f"{active_info}\n\n"
                        f>Please close existing trades or purchase more combines to continue trading.")

        show_trade_limit_alert(popup_message, "All Trade Limits Exceeded")

        return False, error_message

else:
    error_message = "■ No combines configured"
    show_trade_limit_alert("No trading combines configured! Please set up your combine limits.",
                          "Configuration Error")
    return False, error_message

```

Method: TradeLimitManager.get_current_trade_count

```
def get_current_trade_count(self) -> int
```

Get the current number of active trades from MT5

Why these Python concepts were used

- **return type annotation** — Annotated return type -> int. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def get_current_trade_count(self) -> int:
    """Get the current number of active trades from MT5"""
    try:
        return self.get_active_trades_from_mt5()
    except Exception as e:
        logging.error(f"Failed to get current trade count: {e}")
        return 0
```

Method: TradeLimitManager.get_trade_summary

```
def get_trade_summary(self) -> Dict
    Get comprehensive trade limit summary
```

Why these Python concepts were used

- **return type annotation** — Annotated return type -> Dict. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Calls `self.update_active_trades_all_combines(...)` for its side effect.
2. Assigns `summary = {'total_combines': len(self.combines), 'total_max_trades'...`
3. **for** `(combine_id, combine)` in `self.combines.items()`: iterates.
4. **return** summary.

Code (copy-paste safe)

```
def get_trade_summary(self) -> Dict:
    """Get comprehensive trade limit summary"""
    self.update_active_trades_all_combines()

    summary = {
        "total_combines": len(self.combines),
        "total_max_trades": sum(c.max_trades for c in self.combines.values()),
        "total_active_trades": sum(c.active_trades for c in self.combines.values()),
        "total_remaining": sum(c.remaining_trades() for c in self.combines.values()),
        "mt5_active_trades": self.get_active_trades_from_mt5() if self.mt5 else 0,
```

```

        "combines": {}
    }

    for combine_id, combine in self.combines.items():
        summary["combines"][combine_id] = {
            "max_trades": combine.max_trades,
            "active_trades": combine.active_trades,
            "remaining": combine.remaining_trades(),
            "can_trade": combine.can_place_trade(),
            "account_name": combine.account_name
        }

    return summary

```

Method: TradeLimitManager.print_trade_status

```
def print_trade_status(self)
    Print detailed trade status
```

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns summary = self.get_trade_summary().
2. Calls print(...) for its side effect.
3. Calls print(...) for its side effect.
4. Calls print(...) for its side effect.
5. Calls print(...) for its side effect.
6. Calls print(...) for its side effect.
7. Calls print(...) for its side effect.
8. Calls print(...) for its side effect.
9. if summary['combines']: branches conditionally.
10. Assigns (can_trade, reason) = self.can_place_trade().
11. Calls print(...) for its side effect.
12. Calls print(...) for its side effect.

Code (copy-paste safe)

```
def print_trade_status(self):
    """Print detailed trade status"""
    summary = self.get_trade_summary()

    print("\n" + "="*60)
    print("■ TRADE LIMIT STATUS")
    print("="*60)

```

```

print(f"■ Total Combines: {summary['total_combines']}")
print(f"■ Total Trade Capacity: {summary['total_max_trades']}")
print(f"■ Active Trades (MT5): {summary['mt5_active_trades']}")
print(f"■ Available Slots: {summary['total_remaining']}")

if summary['combines']:
    print(f"\n■ COMBINE DETAILS:")
    for combine_id, info in summary['combines'].items():
        status = "■ Available" if info['can_trade'] else "■ Full"
        account_info = f"({info['account_name']})" if info['account_name'] else ""
        print(f"    {combine_id}{account_info}: {info['active_trades']}/{info['max_trades']} {status}")

    can_trade, reason = self.can_place_trade()
    print(f"\n■ TRADE STATUS: {reason}")
    print("="*60)

```

Method: TradeLimitManager.load_combines_from_config

```
def load_combines_from_config(self, config_file: str='combine_config.txt') -> bool
```

Load combine configuration from file

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `config_file: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **return type annotation** — Annotated return type `-> bool`. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

def load_combines_from_config(self, config_file: str = "combine_config.txt") -> bool:
    """Load combine configuration from file"""
    try:
        if not os.path.exists(config_file):
            # Create default config file
            self.create_default_config(config_file)

        with open(config_file, 'r') as f:
            for line in f:
                line = line.strip()

```

```

        if line and not line.startswith('#'):
            parts = line.split(',')
            if len(parts) >= 2:
                combine_id = parts[0].strip()
                max_trades = int(parts[1].strip())
                account_name = parts[2].strip() if len(parts) > 2 else ""
                self.add_combine(combine_id, max_trades, account_name)

        logging.info(f"■ Loaded combines from {config_file}")
        return True

    except Exception as e:
        logging.error(f"■ Failed to load combines from {config_file}: {e}")
        return False

```

Method: TradeLimitManager.create_default_config

```
def create_default_config(self, config_file: str='combine_config.txt')
```

Create default combine configuration file

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `config_file: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

def create_default_config(self, config_file: str = "combine_config.txt"):
    """Create default combine configuration file"""
    try:
        with open(config_file, 'w') as f:
            f.write("# Combine Configuration File\n")
            f.write("# Format: combine_id, max_trades, account_name (optional)\n")
            f.write("# Example: 5_combine, 5, Main Account\n\n")

            f.write("# Default configurations (modify as needed)\n")
            f.write("# 5_combine, 5, Primary\n")
            f.write("# 10_combine, 10, Secondary\n")
            f.write("# 15_combine, 15, Advanced\n")
            f.write("# 20_combine, 20, Professional\n")

        logging.info(f"■ Created default config file: {config_file}")

    except Exception as e:

```

```
logging.error(f"■ Failed to create default config: {e}")
```

Functions

```
def show_trade_limit_alert(message: str, title: str='Trade Limit Exceeded')
```

Show a popup alert when trade limits are exceeded

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `message: str, title: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **if POPUP_AVAILABLE**: branches conditionally (with an **else/elif** arm).

Code (copy-paste safe)

```
def show_trade_limit_alert(message: str, title: str = "Trade Limit Exceeded"):
    """
    Show a popup alert when trade limits are exceeded
    """
    if POPUP_AVAILABLE:
        try:
            # Create a temporary root window (hidden)
            root = tk.Tk()
            root.withdraw() # Hide the main window

            # Show the error message
            messagebox.showerror(title, message)

            # Destroy the root window
            root.destroy()

        except Exception as e:
            logging.error(f"Failed to show popup alert: {e}")
            print(f"■■ Popup alert failed: {message}")
    else:
        # Fallback to console output
        print(f"■ {title}: {message}")
```

```
def check_trade_limit(combine_id: str=None) -> Tuple[bool, str]
```

Quick function to check if a trade can be placed Returns: (can_place, reason)

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., `combine_id: str`). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and

human readers. They are the fastest way to make a public function self-explanatory.

- **return type annotation** — Annotated return type -> Tuple[bool, str]. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. **return** trade_limit_manager.can_place_trade(combine_id).

Code (copy-paste safe)

```
def check_trade_limit(combine_id: str = None) -> Tuple[bool, str]:
    """
    Quick function to check if a trade can be placed
    Returns: (can_place, reason)
    """
    return trade_limit_manager.can_place_trade(combine_id)
```

```
def get_trade_summary() -> Dict
```

Get current trade limit summary

Why these Python concepts were used

- **return type annotation** — Annotated return type -> Dict. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. **return** trade_limit_manager.get_trade_summary().

Code (copy-paste safe)

```
def get_trade_summary() -> Dict:
    """Get current trade limit summary"""
    return trade_limit_manager.get_trade_summary()
```

```
def initialize_trade_limits(config_file: str='combine_config.txt') -> bool
```

Initialize trade limits from configuration

Why these Python concepts were used

- **type-annotated parameters** — Parameters carry type hints (e.g., config_file: str). Hints are not enforced at runtime — they document intent for static checkers (mypy/pyright), IDE auto-complete, and human readers. They are the fastest way to make a public function self-explanatory.

- **return type annotation** — Annotated return type -> bool. Declares the function's contract: callers can rely on this shape, and tools can flag a caller that misuses the result.

Step by step (top-level body)

1. **return** trade_limit_manager.load_combines_from_config(config_file).

Code (copy-paste safe)

```
def initialize_trade_limits(config_file: str = "combine_config.txt") -> bool:
    """Initialize trade limits from configuration"""
    return trade_limit_manager.load_combines_from_config(config_file)
```

Step 7.4 — Build trader_companion/hedge_protector.py

What to do. Create the file trader_companion/hedge_protector.py in your project root and paste in the code shown in this step. The file is **576** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from requirements.txt.

What this file is for. The hedging engine. Watches a primary account for net exposure and opens offsetting positions on a hedge account so that drawdown on the funded leg is bounded.

trader_companion/hedge_protector.py

576 loc · 1 classes · 0 functions · 6 imports

The hedging engine. Watches a primary account for net exposure and opens offsetting positions on a hedge account so that drawdown on the funded leg is bounded. It defines **1** class, across **576** lines.

Module docstring: *Hedge Protector — Double-SL Prevention Engine*

Module docstring

Hedge Protector — Double-SL Prevention Engine

Monitors both MT5 and Tradovate positions in real-time. When a trade closes via SL on one side, immediately closes the hedge on the other side. When a trade closes via TP, leaves the hedge running (chance for double TP).

Matching: MT5 comment format = "{TradovateAccountNumber}_{PhaseCode}" e.g., "FNFTCHHARRISONOUKA85625_CH1", "MFFU_EV_ST_P326057008_FD1"

Architecture: - MT5: Polls positions every 500ms, detects removals - Tradovate: REST polling every 5s for position change detection - Engine: Matches pairs, determines SL vs TP, triggers close

Python concepts demonstrated in this module

• Classes and objects • Decorators • Dunder methods • Exceptions • f-strings • Lambdas • Properties

Imports — what each one is for

import time

Why imported. Timestamps and sleep. Lower-level than datetime — works in Unix-epoch seconds.

Used in this file. time.sleep

Example. time.sleep(1.5) # pause this thread for 1.5 seconds

Other common scenarios.

- time.time() returns seconds since the epoch

- `time.monotonic()` for measuring elapsed time (never goes backward)
- `time.perf_counter()` for high-precision benchmarking
- `time.strptime` / `time.strftime` mirror the `datetime` versions

`import json`

Why imported. JSON encoding and decoding — the standard wire format for config files, API payloads, and inter-process messages.

Used in this file. *No direct attribute access detected — likely imported for side effects, re-export, or string references.*

Example. `json.loads(response.text)` # parse a JSON string to dict

Other common scenarios.

- `json.dumps(obj, indent=2)` for pretty-printing
- `json.dump(obj, file)` / `json.load(file)` for file I/O
- `default=str` handles non-serialisable types like `datetime`
- `object_hook=` customises decoding (e.g., to `dataclass` instances)

`import threading`

Why imported. Threads and synchronisation primitives. Used when work is I/O-bound and the GIL is not a bottleneck (the GIL prevents speed-up on CPU-bound work).

Used in this file. `threading.Thread`

Example. `Thread(target=worker, args=(q,), daemon=True).start()`

Other common scenarios.

- `Lock` / `RLock` to guard shared state
- `Event` for one-shot signals between threads
- `Queue` (from `queue`) for producer/consumer patterns
- `threading.local()` for thread-local storage

`import logging`

Why imported. Structured, levelled logging. Replaces `print()` with filterable, formattable output that can route to files, `stderr`, `syslog`, or HTTP endpoints.

Used in this file. *No direct attribute access detected — likely imported for side effects, re-export, or string references.*

Example. `logging.getLogger(__name__).info('connected to %s', host)`

Other common scenarios.

- `.debug()` / `.info()` / `.warning()` / `.error()` / `.exception()`
- `logger.exception()` captures the current traceback automatically
- `logging.basicConfig(level=logging.INFO)` for quick setup
- `Handlers` and `Formatters` route logs to files / streams / `syslog`

```
from datetime import datetime
from datetime import timezone
```

Why imported. Dates, times, durations. The fundamental temporal types: date, time, datetime, timedelta, timezone.

Used in this file. *No direct attribute access detected — likely imported for side effects, re-export, or string references.*

Example. `datetime.now() - timedelta(days=7)` # one week ago

Other common scenarios.

- `datetime.strptime(s, '%Y-%m-%d')` parses a string
- `datetime.strftime(fmt)` formats one
- `datetime.fromtimestamp(n)` converts a Unix epoch
- `datetime.utcnow()` for UTC (better: `datetime.now(timezone.utc)`)

```
from collections import defaultdict
```

Why imported. Specialised container datatypes that the dict / list / tuple / set primitives don't cover.

Used in this file. *No direct attribute access detected — likely imported for side effects, re-export, or string references.*

Example. `Counter(words)` # multiset that counts occurrences

Other common scenarios.

- `defaultdict(list)` auto-creates a default value on missing keys
- `deque(maxlen=N)` is a double-ended bounded queue
- `OrderedDict` (mostly redundant since 3.7 — dicts preserve order)
- `namedtuple('Point', 'x y')` for tiny immutable record types

Classes

```
class HedgeProtector
```

Real-time hedge protection engine. Monitors MT5 and Tradovate positions. When a position closes: - If SL hit → close the matching hedge on the other platform - If TP hit → do nothing (let hedge run for potential double TP) Usage: protector = HedgeProtector(mt5_api=mt5_api_instance, tradovate_accounts={firm_name: tradovate_account_instance, ...}, on_event=callback_fn, # (event_type, message) for UI logging) protector.start() ... protector.stop()

Code (copy-paste safe)

```

Why these Python concepts were used

- **lambda** — Uses a single-expression anonymous function — typically as the key= for a sort, the filter predicate, or a small callback.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **__init__** — The constructor. Runs after Python has allocated the instance; assigns starting attribute values to self.

Step by step (top-level body)

1. Assigns self.mt5_api = mt5_api.
2. Assigns self.tradovate_accounts = tradovate_accounts or {}.
3. Assigns self.on_event = on_event or (lambda t, m: print(f'[HEDGE {t.upper()}] {m}')).
4. Assigns self.on_status_change = on_status_change.
5. Assigns self._running = False.
6. Assigns self._mt5_thread = None.
7. Assigns self._tv_threads = {}.
8. Assigns self._mt5_positions = {}.
9. Assigns self._tv_positions = {}.
10. Assigns self._tv_account_info = {}.
11. Assigns self._closed_hedges = set().
12. Assigns self.stats = {'sl_protected': 0, 'tp_passed': 0, 'errors': 0, 'mt5_pol....

Code (copy-paste safe)

```

```

Method: HedgeProtector.stop

```
def stop(self)

    Stop all monitoring.
```

Step by step (top-level body)

1. Assigns `self._running = False`.
2. Calls `self.on_event(...)` for its side effect.
3. Calls `self._tv_threads.clear(...)` for its side effect.
4. Calls `self.on_event(...)` for its side effect.

Code (copy-paste safe)

```
def stop(self):
    """Stop all monitoring."""
    self._running = False
    self.on_event("info", "Hedge Protector stopping...")

    # Stop all Tradovate polling threads
    self._tv_threads.clear()
    self.on_event("info", "Hedge Protector stopped")
```

Method: HedgeProtector.is_running

```
@property
def is_running(self)
```

Why these Python concepts were used

- **@property** — Wrapped in **@property** so callers access the value with attribute syntax (`obj.x`) instead of a method call. Lets the implementation compute or validate the value lazily without changing the call site.

Step by step (top-level body)

1. **return** `self._running`.

Code (copy-paste safe)

```
def is_running(self):
    return self._running
```

Method: HedgeProtector._mt5_poll_loop

```
def _mt5_poll_loop(self)
```

Poll MT5 positions every 500ms, detect closures.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **while** self._running: loops until the condition is false.

Code (copy-paste safe)

```
def _mt5_poll_loop(self):
    """Poll MT5 positions every 500ms, detect closures."""
    while self._running:
        try:
            self._mt5_check_positions()
            self.stats["mt5_polls"] += 1
        except Exception as e:
            self.on_event("error", f"MT5 poll error: {e}")
            self.stats["errors"] += 1
        time.sleep(0.5)
```

Method: HedgeProtector._mt5_check_positions

```
def _mt5_check_positions(self)
```

Snapshot MT5 positions and detect any that disappeared (closed).

Step by step (top-level body)

1. **if** not mt5: branches conditionally.
2. Assigns positions = mt5.positions_get().
3. Assigns current = {}.
4. **if** positions: branches conditionally.
5. **for** (ticket, prev_pos) in self._mt5_positions.items(): iterates.
6. Assigns self._mt5_positions = current.

Code (copy-paste safe)

```
def _mt5_check_positions(self):
    """Snapshot MT5 positions and detect any that disappeared (closed)."""
    if not mt5:
        return

            except Exception as _sc_e:
                self.on_event("error", f"Status change callback failed: {_sc_e}")
```

Method: HedgeProtector._close_mt5_hedge

```
def _close_mt5_hedge(self, tv_account_name, tv_contract_id)
```

Close the matching MT5 position when Tradovate SL is hit.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **if** not self.mt5_api or not mt5: branches conditionally.
2. Calls self.on_event(...) for its side effect.
3. Assigns positions = mt5.positions_get().
4. **if** not positions: branches conditionally.
5. Assigns closed_count = 0.
6. **for** pos in positions: iterates.
7. **if** closed_count == 0: branches conditionally (with an **else/elif** arm).

Code (copy-paste safe)

```
def _close_mt5_hedge(self, tv_account_name, tv_contract_id):
    """Close the matching MT5 position when Tradovate SL is hit."""
    if not self.mt5_api or not mt5:
        self.on_event("error", "Cannot close MT5 hedge – MT5 not connected")
        return

    self.on_event("close_sent",
                  f"■■■ Closing MT5 hedge for Tradovate account {tv_account_name} (Tradovate SL hit)")

    # Find MT5 positions whose comment contains this Tradovate account
    positions = mt5.positions_get()
    if not positions:
        self.on_event("warn", "No open MT5 positions found")
        return

    closed_count = 0
    for pos in positions:
        comment = getattr(pos, 'comment', '')
        if not comment:
            continue
        # Check if comment references this Tradovate account
        if tv_account_name in comment:
            self.on_event("close_sent",
                          f"■■■ Closing MT5 #{pos.ticket} {pos.symbol} (comment: {comment})")
            try:
                success = self.mt5_api.close_trade(pos.ticket)
                if success:
                    self.on_event("close_sent",
                                  f"■ MT5 #{pos.ticket} closed successfully")
                    closed_count += 1
                else:

    return None

```

Method: HedgeProtector._cancel_tradovate_orders

```
def _cancel_tradovate_orders(self, tv_account_number)
```

Cancel all pending Tradovate orders for the given account number.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **for** (firm_name, tv_account) in self.tradovate_accounts.items(): iterates.

Code (copy-paste safe)

```
def _cancel_tradovate_orders(self, tv_account_number):
    """Cancel all pending Tradovate orders for the given account number."""
    for firm_name, tv_account in self.tradovate_accounts.items():
        try:
            acct_info = self._tv_account_info.get(firm_name, {})
            acct_name = acct_info.get('name', '')
            acct_id = acct_info.get('id')
            if tv_account_number in acct_name or acct_name in tv_account_number:
                if hasattr(tv_account, 'cancel_all_orders_api'):
                    cancelled = tv_account.cancel_all_orders_api(account_id=acct_id)
                    if cancelled > 0:
                        self.on_event("info",
                                      f"■ Cancelled {cancelled} Tradovate order(s) for {acct_name}")
                return
            # Check all accounts under this connection
            accounts = tv_account._api_fetch("/account/list")
            if accounts:
                for acct in accounts:
                    name = acct.get('name', '')
                    if tv_account_number in name or name in tv_account_number:
                        if hasattr(tv_account, 'cancel_all_orders_api'):
                            cancelled = tv_account.cancel_all_orders_api(account_id=acct['id'])
                            if cancelled > 0:
                                self.on_event("info",
                                              f"■ Cancelled {cancelled} Tradovate order(s) for {name}")
                return
        except Exception as e:
            self.on_event("error", f"Failed to cancel Tradovate orders for {firm_name}: {e}")
```

Method: HedgeProtector._cancel_tradovate_orders_by_firm

```
def _cancel_tradovate_orders_by_firm(self, firm_name)
```

Cancel all pending Tradovate orders for a specific firm connection.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `tv_account = self.tradovate_accounts.get(firm_name)`.
2. **if** not `tv_account` or not `hasattr(tv_account, 'cancel_all_orders_api')`: branches conditionally.
3. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def _cancel_tradovate_orders_by_firm(self, firm_name):
    """Cancel all pending Tradovate orders for a specific firm connection."""
    tv_account = self.tradovate_accounts.get(firm_name)
    if not tv_account or not hasattr(tv_account, 'cancel_all_orders_api'):
        return
    try:
        acct_info = self._tv_account_info.get(firm_name, {})
        acct_id = acct_info.get('id')
        cancelled = tv_account.cancel_all_orders_api(account_id=acct_id)
        if cancelled > 0:
            self.on_event("info", f"■ Cancelled {cancelled} Tradovate order(s) for {firm_name}")
    except Exception as e:
        self.on_event("error", f"Failed to cancel Tradovate orders for {firm_name}: {e}")
```

Method: HedgeProtector._tv_rest_poll_loop

```
def _tv_rest_poll_loop(self, firm_name, tv_account)

    Poll Tradovate positions via REST API every 5 seconds.
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `prev_positions = {}`.
2. **while** `self._running`: loops until the condition is false.

Code (copy-paste safe)

```
def _tv_rest_poll_loop(self, firm_name, tv_account):
    """Poll Tradovate positions via REST API every 5 seconds."""
    prev_positions = {}

    while self._running:
        try:
            positions = tv_account.get_positions_api()
            current = {}
            for p in positions:
                key = (p.get('accountId', 0), p.get('contractId', 0))
                current[key] = p.get('netPos', 0)
```

```

        # Detect positions that went to 0
        for key, prev_net in prev_positions.items():
            cur_net = current.get(key, 0)
            if prev_net != 0 and cur_net == 0:
                # Position closed
                entity = {'accountId': key[0], 'contractId': key[1], 'netPos': 0,
                          'boughtValue': 0, 'soldValue': 0}
                self._on_tradovate_position_closed(firm_name, tv_account, entity, prev_net)

        prev_positions = current
        self.stats["tv_events"] += 1

    except Exception as e:
        self.on_event("error", f"Tradovate REST poll error ({firm_name}): {e}")
        self.stats["errors"] += 1

    time.sleep(5)

```

Method: HedgeProtector.get_status

```
def get_status(self)
```

Return current status for UI display.

Step by step (top-level body)

1. Assigns `mt5_count = len(self._mt5_positions)`.
2. Assigns `tv_firms = len(self._tv_threads)`.
3. **return** `{'running': self._running, 'mt5_positions': mt5_count, 'tv_connecti....`

Code (copy-paste safe)

```

def get_status(self):
    """Return current status for UI display."""
    mt5_count = len(self._mt5_positions)
    tv_firms = len(self._tv_threads)
    return {
        "running": self._running,
        "mt5_positions": mt5_count,
        "tv_connections": tv_firms,
        "sl_protected": self.stats["sl_protected"],
        "tp_passed": self.stats["tp_passed"],
        "errors": self.stats["errors"],
    }

```

Method: HedgeProtector.clear_closed_cache

```
def clear_closed_cache(self)
```

Clear the closed hedge cache (for re-monitoring after restart).

Step by step (top-level body)

1. Calls `self._closed_hedges.clear(...)` for its side effect.

Code (copy-paste safe)

```

def clear_closed_cache(self):
    """Clear the closed hedge cache (for re-monitoring after restart)."""

```

```
self._closed_hedges.clear()
```

Checkpoint — what works now. The trading engine is complete. With MT5 running and a logged-in account, `mt5_trading.MT5Trader().place_order(...)` sends real orders; `trade_limit_manager` blocks ones that would breach daily limits; `hedge_protector` can open offsetting positions on a hedge account. Test on a demo account before pointing it at anything live.

Chapter 8 — Phase 6 — Prop-firm dashboards

Funded accounts live behind prop-firm dashboards (Topstep, FundedNext, Tradovate, TradeOpss) that have no official API. We use Selenium and the Chrome DevTools Protocol to log in, read account state, and post it to our own database. We build a base scraper class first, then the firm-specific subclasses, then a manager that coordinates them.

Files we build in this phase, in order:

- `trader_companion/prop_firm_scrapers.py`
- `trader_companion/fundednext.py`
- `trader_companion/topstepx.py`
- `trader_companion/tradovate.py`
- `trader_companion/prop_firm_manager.py`

Python concepts you'll meet in this phase

- Dunder methods (5) · Classes and objects (5) · f-strings (5) · Comprehensions (5) · Exceptions (4) · Context managers (with-statements) (4) · Decorators (2) · Module-level state (1)

Each is explained in Chapter 2 (the primer). The number in parentheses is how many of this phase's files use that concept.

Step 8.1 — Build `trader_companion/prop_firm_scrapers.py`

What to do. Create the file `trader_companion/prop_firm_scrapers.py` in your project root and paste in the code shown in this step. The file is **1893** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from `requirements.txt`.

What this file is for. Browser-automation scrapers (Selenium / Chrome DevTools Protocol) that pull account state out of prop-firm dashboards that have no official API.

`trader_companion/prop_firm_scrapers.py`

1893 loc · 6 classes · 5 functions · 10 imports

Browser-automation scrapers (Selenium / Chrome DevTools Protocol) that pull account state out of prop-firm dashboards that have no official API. It defines **6** classes and **5** module-level functions, across **1,893** lines. Module docstring: *Prop Firm Dashboard Scrapers — CDP-based (no Selenium required)*

Module docstring

Prop Firm Dashboard Scrapers — CDP-based (no Selenium required) Scrapes account data from Tradeify, Lucid Trading, TopStep, and MFFU dashboards via Chrome DevTools Protocol connecting to an already-open Chrome debug port.

Each class follows the standard interface: - login() → attach to existing Chrome tab, verify logged in - get_account_stats() → basic account info for GUI display - get_billing_history() → subscription/purchase history - get_payouts() → payout history - get_all_accounts() → all accounts - is_connected() → bool - close() / disconnect()

Requires Chrome running with: --remote-debugging-port=9222 --remote-allow-origins=*
--user-data-dir="<path>"

Python concepts demonstrated in this module

- Classes and objects
- Comprehensions
- Context managers (with-statements)
- Dunder methods
- Exceptions
- f-strings
- Module-level state
- Inheritance

Imports — what each one is for

```
import json
```

Why imported. JSON encoding and decoding — the standard wire format for config files, API payloads, and inter-process messages.

Used in this file. json.JSONDecodeError, json.dumps, json.loads

Example. json.loads(response.text) # parse a JSON string to dict

Other common scenarios.

- json.dumps(obj, indent=2) for pretty-printing
- json.dump(obj, file) / json.load(file) for file I/O
- default=str handles non-serialisable types like datetime
- object_hook= customises decoding (e.g., to dataclass instances)

```
import logging
```

Why imported. Structured, levelled logging. Replaces print() with filterable, formattable output that can route to files, stderr, syslog, or HTTP endpoints.

Used in this file. logging.INFO, logging.basicConfig, logging.getLogger

Example. logging.getLogger(__name__).info('connected to %s', host)

Other common scenarios.

- .debug() / .info() / .warning() / .error() / .exception()

- `logger.exception()` captures the current traceback automatically
- `logging.basicConfig(level=logging.INFO)` for quick setup
- Handlers and Formatters route logs to files / streams / syslog

`import os`

Why imported. Operating-system interface. Path manipulation, environment variables, working-directory operations, exit codes, and thin wrappers around POSIX/Windows syscalls.

Used in this file. `os.environ`, `os.environ.get`, `os.path`, `os.path.isfile`, `os.path.join`

Example. `os.path.join(root, 'subdir', 'file.txt')` # joins with the OS-correct separator

Other common scenarios.

- `os.environ.get('API_KEY')` to read environment variables
- `os.makedirs(path, exist_ok=True)` to create nested directories
- `os.listdir(path)` to list a directory's contents
- `os.remove(path)` / `os.rename(src, dst)` to delete or move a file
- `os.getcwd()` / `os.chdir(path)` to inspect or change the working dir

`import re`

Why imported. Regular expressions. Pattern matching, search, replace, and text extraction.

Used in this file. *No direct attribute access detected — likely imported for side effects, re-export, or string references.*

Example. `re.search(r'\d{3}-\d{4}', text)` # returns a Match or None

Other common scenarios.

- `re.findall(pattern, text)` for every non-overlapping match
- `re.sub(pattern, repl, text)` to replace occurrences
- `re.compile(...)` to reuse a pattern (faster in a loop)
- Named groups: `r'(?P<year>\d{4})'` lets you do `m.group('year')`

`import shutil`

Why imported. High-level filesystem operations: copying trees, moving files across filesystems, deleting directories, locating executables on PATH.

Used in this file. `shutil.which`

Example. `shutil.copytree(src, dst)` # recursively copies a tree

Other common scenarios.

- `shutil.move(src, dst)` moves or renames
- `shutil.rmtree(path)` deletes a directory and all its contents
- `shutil.which('git')` finds an executable on PATH
- `shutil.disk_usage(path)` returns total / used / free bytes

```
import subprocess
```

Why imported. Run external programs. The standard way to spawn a child process, capture its output, and wait for its exit code.

Used in this file. `subprocess.DEVNULL`, `subprocess.Popen`

Example. `subprocess.run(['git', 'rev-parse', 'HEAD'], capture_output=True, text=True, check=True)`

Other common scenarios.

- `Popen(...)` for streaming I/O while the process is alive
- `check_output(cmd)` returns stdout as text and raises on failure
- `DEVNULL` / PIPE redirect stdin/stdout/stderr
- `shell=True` interprets the string with the system shell (security risk)

```
import threading
```

Why imported. Threads and synchronisation primitives. Used when work is I/O-bound and the GIL is not a bottleneck (the GIL prevents speed-up on CPU-bound work).

Used in this file. `threading.Lock`, `threading.RLock`

Example. `Thread(target=worker, args=(q,), daemon=True).start()`

Other common scenarios.

- `Lock` / `RLock` to guard shared state
- `Event` for one-shot signals between threads
- `Queue` (from `queue`) for producer/consumer patterns
- `threading.local()` for thread-local storage

```
import time
```

Why imported. Timestamps and sleep. Lower-level than `datetime` — works in Unix-epoch seconds.

Used in this file. `time.sleep`, `time.time`

Example. `time.sleep(1.5)` # pause this thread for 1.5 seconds

Other common scenarios.

- `time.time()` returns seconds since the epoch
- `time.monotonic()` for measuring elapsed time (never goes backward)
- `time.perf_counter()` for high-precision benchmarking
- `time.strftime` / `time.strptime` mirror the `datetime` versions

```
import urllib.request
```

Why imported. Stdlib URL utilities — parsing, encoding, and a basic HTTP client. Mostly useful for the parsing helpers; for outbound HTTP, requests is more pleasant.

Used in this file. *No direct attribute access detected — likely imported for side effects, re-export, or string references.*

Example. `urllib.parse.urlencode({'q': 'hello world'})`

Other common scenarios.

- `urllib.parse.urlparse(url)` splits scheme/host/path/query
- `urllib.parse.quote(s)` percent-encodes a path segment
- `urllib.request.urlopen(url)` is the basic HTTP client

```
import urllib.parse
```

Why imported. Stdlib URL utilities — parsing, encoding, and a basic HTTP client. Mostly useful for the parsing helpers; for outbound HTTP, requests is more pleasant.

Used in this file. `urllib.parse`, `urllib.parse.quote`, `urllib.request`, `urllib.request.Request`, `urllib.request.urlopen`

Example. `urllib.parse.urlencode({'q': 'hello world'})`

Other common scenarios.

- `urllib.parse.urlparse(url)` splits scheme/host/path/query
- `urllib.parse.quote(s)` percent-encodes a path segment
- `urllib.request.urlopen(url)` is the basic HTTP client

Module constants

Each line below is followed by a plain-English note explaining what it does and why it is written that way.

```
CDP_DEBUG_PORT = 9222
```

Numeric literal — a tunable parameter compiled into the source.

```
CDP_USER_DATA_DIR = os.path.join(os.environ.get('LOCALAPPDATA', ''), 'Google', 'Chrome', 'User Data CDP')
```

Module-level constant — bound once at import time and referenced from the functions and classes below.

Classes

```
class CDPBase
```

Base class for CDP-based prop firm scrapers. Connects to a Chrome tab via WebSocket and executes JS fetch() calls from the browser context to use the site's session cookies/tokens.

```
DOMAIN = ''
FIRM_NAME = ''
_msg_id = 0
```

Code (copy-paste safe)

```
class CDPBase:
    """
    Base class for CDP-based prop firm scrapers.
    Connects to a Chrome tab via WebSocket and executes JS fetch() calls
    from the browser context to use the site's session cookies/tokens.
    """

    DOMAIN = ""          # Override in subclasses: e.g. "app-f.tradeify.co"
    FIRM_NAME = ""        # Override: e.g. "Tradeify"
    _msg_id = 0
```

```

def __init__(self, debug_port=9222, pair_id="default"):

```

Method: CDPBase.__init__

```
def __init__(self, debug_port=9222, pair_id='default')
```

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **__init__** — The constructor. Runs after Python has allocated the instance; assigns starting attribute values to self.

Step by step (top-level body)

1. Assigns `self.debug_port = debug_port`.
2. Assigns `self.pair_id = pair_id`.
3. Assigns `self.ws = None`.
4. Assigns `self.tab_url = None`.
5. Assigns `self.logged_in = False`.
6. Assigns `self._login_timestamp = None`.
7. Assigns `self._cached_stats = None`.
8. Assigns `self._stats_last_fetch = 0`.
9. Assigns `self.lock = threading.RLock()`.
10. Assigns `self.logger = logging.getLogger(f'{self.FIRM_NAME}_{pair_id}')`.

Code (copy-paste safe)

```
def __init__(self, debug_port=9222, pair_id="default"):
    self.debug_port = debug_port
    self.pair_id = pair_id
    self.ws = None
    self.tab_url = None
    self.logged_in = False
    self._login_timestamp = None
    self._cached_stats = None
    self._stats_last_fetch = 0
    self.lock = threading.RLock()
    self.logger = logging.getLogger(f"{self.FIRM_NAME}_{pair_id}")
```

Method: CDPBase._find_tab

```
def _find_tab(self)
```

Find the browser tab matching this firm's domain.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.
2. **return None**.

Code (copy-paste safe)

```
def _find_tab(self):
    """Find the browser tab matching this firm's domain."""
    try:
        data = urllib.request.urlopen(
            f'http://127.0.0.1:{self.debug_port}/json', timeout=5
        ).read()
        tabs = json.loads(data)
        for t in tabs:
            if t.get('type') == 'page' and self.DOMAIN in t.get('url', ''):
                return t
    except Exception as e:
        self.logger.error(f"[CDP] Failed to list tabs: {e}")
    return None
```

Method: CDPBase._connect_ws

```
def _connect_ws(self, tab)
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't

have to handle it.

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **raise** — Raises an exception explicitly. Either signals an invalid argument the caller should fix, or re-raises after logging.

Step by step (top-level body)

1. Assigns `ws_url = tab.get('webSocketDebuggerUrl')`.
2. `if not ws_url`: branches conditionally.
3. Assigns `target_id = tab.get('id', '')`.
4. `if target_id`: branches conditionally.
5. Assigns `self.ws = websocket.create_connection(ws_url, timeout=30)`.
6. Assigns `self.tab_url = tab.get('url')`.
7. Calls `self.logger.info(...)` for its side effect.

Code (copy-paste safe)

```
def _connect_ws(self, tab):
    """Connect WebSocket to a specific tab."""
    ws_url = tab.get('webSocketDebuggerUrl')
    if not ws_url:
        raise ConnectionError(f"No webSocketDebuggerUrl for tab: {tab.get('url')}")
    # Activate the target first – Chrome requires this for CDP to respond
    target_id = tab.get('id', '')
    if target_id:
        try:
            urllib.request.urlopen(
                f'http://127.0.0.1:{self.debug_port}/json/activate/{target_id}',
                timeout=5
            )
        except Exception:
            pass # Non-critical, continue anyway
    self.ws = websocket.create_connection(ws_url, timeout=30)
    self.tab_url = tab.get('url')
    self.logger.info(f"[CDP] Connected to {self.tab_url}")
```

Method: CDPBase._send

```
def _send(self, method, params=None, timeout=30)
```

Send a CDP command and return the result.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

- **raise** — Raises an exception explicitly. Either signals an invalid argument the caller should fix, or re-raises after logging.

Step by step (top-level body)

1. Updates `CDPBase._msg_id` in place (Add).
2. Assigns `msg_id = CDPBase._msg_id`.
3. Assigns `msg = {'id': msg_id, 'method': method}`.
4. **if** `params`: branches conditionally.
5. Calls `self.ws.send(...)` for its side effect.
6. Assigns `deadline = time.time() + timeout`.
7. Assigns `old_timeout = self.ws.gettimeout()`.
8. **try** block with 0 **except** clauses, plus a **finally**.
9. **raise** `TimeoutError(f'CDP response timeout for {method}')`.

Code (copy-paste safe)

```
def _send(self, method, params=None, timeout=30):
    """Send a CDP command and return the result."""
    CDPBase._msg_id += 1
    msg_id = CDPBase._msg_id
    msg = {'id': msg_id, 'method': method}
    if params:
        msg['params'] = params
    self.ws.send(json.dumps(msg))
    # Read responses until we get our ID back, skipping CDP events
    deadline = time.time() + timeout
    old_timeout = self.ws.gettimeout()
    try:
        while time.time() < deadline:
            self.ws.settimeout(max(0.1, deadline - time.time()))
            try:
                resp = json.loads(self.ws.recv())
            except websocket.WebSocketTimeoutException:
                continue
            if resp.get('id') == msg_id:
                return resp
            # Skip CDP events (no 'id' field)
    finally:
        self.ws.settimeout(old_timeout)
    raise TimeoutError(f"CDP response timeout for {method}")
```

Method: `CDPBase._js`

```
def _js(self, expression, await_promise=False, timeout=None)
```

Execute JavaScript in the page and return the result value.

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

- **raise** — Raises an exception explicitly. Either signals an invalid argument the caller should fix, or re-raises after logging.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns `params = {'expression': expression, 'returnByValue': True}`.
2. `if await_promise:` branches conditionally.
3. Assigns `resp = self._send('Runtime.evaluate', params, timeout=timeout or....)`
4. Assigns `result = resp.get('result', {}).get('result', {})`.
5. `if result.get('subtype') == 'error':` branches conditionally.
6. `return result.get('value')`.

Code (copy-paste safe)

```
def _js(self, expression, await_promise=False, timeout=None):
    """Execute JavaScript in the page and return the result value."""
    params = {'expression': expression, 'returnByValue': True}
    if await_promise:
        params['awaitPromise'] = True
    resp = self._send('Runtime.evaluate', params, timeout=timeout or (30 if await_promise else 10))
    result = resp.get('result', {}).get('result', {})
    if result.get('subtype') == 'error':
        desc = result.get('description', 'JS error')
        raise RuntimeError(f"JS error: {desc}")
    return result.get('value')
```

Method: CDPBase._fetch_json

```
def _fetch_json(self, url, method='GET', body=None, extra_headers=None)
```

Execute a fetch() call from the browser context and parse JSON response.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `headers = {'Content-Type': 'application/json'}`.
2. `if extra_headers:` branches conditionally.
3. `if body and method == 'POST':` branches conditionally (with an **else/elif** arm).
4. Assigns `raw = self._js(js, await_promise=True)`.
5. `if not raw:` branches conditionally.
6. Assigns `result = json.loads(raw)`.

7. Assigns `status = result.get('status', 0)`.
8. `if status != 200`: branches conditionally.
9. `try` block with 1 **except** clause.

Code (copy-paste safe)

```
def _fetch_json(self, url, method='GET', body=None, extra_headers=None):
    """Execute a fetch() call from the browser context and parse JSON response."""
    headers = {'Content-Type': 'application/json'}

Check if the WebSocket connection is alive.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

def is_connected(self):
    """Check if the WebSocket connection is alive."""
    try:
        if not self.ws or not self.ws.connected:
            return False
        # Quick ping with short timeout
        self._send('Runtime.evaluate',
                    {'expression': '1+1', 'returnByValue': True},
                    timeout=5)
        return True
    except Exception:
        self.logged_in = False
        return False

```

Method: CDPBase.disconnect

```
def disconnect(self)
```

Close the WebSocket (does NOT close the Chrome tab).

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't

have to handle it.

Step by step (top-level body)

1. Assigns `self.logged_in = False`.
2. `if self.ws:` branches conditionally.

Code (copy-paste safe)

```
def disconnect(self):
    """Close the WebSocket (does NOT close the Chrome tab)."""
    self.logged_in = False
    if self.ws:
        try:
            self.ws.close()
        except Exception:
            pass
    self.ws = None
```

Method: CDPBase.close

```
def close(self)
```

Alias for disconnect.

Step by step (top-level body)

1. Calls `self.disconnect(...)` for its side effect.

Code (copy-paste safe)

```
def close(self):
    """Alias for disconnect."""
    self.disconnect()
```

Method: CDPBase.get_account_stats

```
def get_account_stats(self)
```

Override in subclasses.

Step by step (top-level body)

1. `return {}`.

Code (copy-paste safe)

```
def get_account_stats(self):
    """Override in subclasses."""
    return {}
```

Method: CDPBase.get_billing_history

```
def get_billing_history(self)
```

Override in subclasses.

Step by step (top-level body)

1. `return []`.

Code (copy-paste safe)

```
def get_billing_history(self):
    """Override in subclasses."""
    return []
```

Method: CDPBase.get_all_accounts

```
def get_all_accounts(self)

    Override in subclasses.
```

Step by step (top-level body)

1. return [].

Code (copy-paste safe)

```
def get_all_accounts(self):
    """Override in subclasses."""
    return []
```

Method: CDPBase.get_payouts

```
def get_payouts(self)

    Override in subclasses.
```

Step by step (top-level body)

1. return [].

Code (copy-paste safe)

```
def get_payouts(self):
    """Override in subclasses."""
    return []
```

```

Method: TradeifyAccount._get_profile

```
def _get_profile(self)
```

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **return** self._fetch_json(f'{self.BASE}/api/auth/profile/').

Code (copy-paste safe)

```
def _get_profile(self):
    return self._fetch_json(f'{self.BASE}/api/auth/profile/')
```

Method: TradeifyAccount._get_broker_credentials

```
def _get_broker_credentials(self)
```

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **return** self._fetch_json(f'{self.BASE}/api/dashboard/broker-credentials').

Code (copy-paste safe)

```
def _get_broker_credentials(self):
    return self._fetch_json(f'{self.BASE}/api/dashboard/broker-credentials')
```

Method: TradeifyAccount._get_account_overview

```
def _get_account_overview(self)
```

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **return** self._fetch_json(f'{self.BASE}/api/dashboard/account-overview?hide_....

Code (copy-paste safe)

```
def _get_account_overview(self):
    return self._fetch_json(

```

Method: TradeifyAccount.get_account_stats

```
def get_account_stats(self)
```

Return account stats from Tradeify account-overview + broker credentials.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **with self.lock**: enters a context manager.

Code (copy-paste safe)

```
def get_account_stats(self):
    """Return account stats from Tradeify account-overview + broker credentials."""

return stats

```

Method: TradeifyAccount.get_billing_history

```
def get_billing_history(self)
```

Get order history as billing records with Tradovate account linking.

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns `billing = []`.
2. Assigns `page = 1`.
3. **while** `True`: loops until the condition is false.
4. **return** `billing`.

Code (copy-paste safe)

```
def get_billing_history(self):
    """Get order history as billing records with Tradovate account linking."""
    billing = []
    page = 1
    while True:
        result = self._fetch_json(

```

Method: TradeifyAccount.get_account_mapping

```
def get_account_mapping(self)
```

Map Tradeify broker_account_id -> Tradovate account info. Uses get-order-list (broker_account has tradovate account_id) and account-overview (has broker_account_id + account_id) to build a mapping keyed by broker_account_id.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns mapping = {}.
2. Assigns overview = self._fetch_json(f'{self.BASE}/api/dashboard/account-over....
3. **if** overview and overview.get('success'): branches conditionally.
4. Calls self.logger.info(...) for its side effect.
5. **return** mapping.

Code (copy-paste safe)

```
def get_account_mapping(self):
    """Map Tradeify broker_account_id -> Tradovate account info.

    Uses get-order-list (broker_account has tradovate account_id) and
    account-overview (has broker_account_id + account_id) to build
    a mapping keyed by broker_account_id.
    """
    mapping = {}
    # account-overview gives broker_account_id -> account_id
    overview = self._fetch_json(

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.

Step by step (top-level body)

```

Method: TopStepAccount._fetch_ts

```
def _fetch_ts(self, path, params=None)
```

Fetch from TopStep REST API with cookies.

Why these Python concepts were used

- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns url = f'{self.REST_BASE}{path}'.
2. if params: branches conditionally.
3. return self._fetch_json(url).

Code (copy-paste safe)

```

def _fetch_ts(self, path, params=None):
    """Fetch from TopStep REST API with cookies."""
    url = f"{self.REST_BASE}{path}"
    if params:
        qs = '&'.join(f"{k}={v}" for k, v in params.items())
        url += f"?{qs}"
    return self._fetch_json(url)

```

Method: TopStepAccount._graphql

```
def _graphql(self, query, variables=None)
```

Execute a GraphQL query against TopStep's Crystal endpoint.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns body = {'query': query}.
2. if variables: branches conditionally.

3. Assigns headers = {'Content-Type': 'application/json'}.
4. Assigns js = f""" (async () => {{\n const r

    user = profile.get('user', profile)
    if isinstance(user, dict):
        uid = user.get('id', user.get('userId', user.get('legacyAppId')))
        if uid:
            return uid
        inner = user.get('user', {})
        if isinstance(inner, dict):
            return inner.get('legacyAppId', inner.get('id'))
    return None
```

Method: TopStepAccount._get_email

```
def _get_email(self)
```

Extract email from profile.

Why these Python concepts were used

- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.

Step by step (top-level body)

1. Assigns `profile = self._get_profile()`.
2. **if not profile:** branches conditionally.
3. Assigns `user = profile.get('user', profile)`.
4. **if isinstance(user, dict):** branches conditionally.
5. **return None.**

Code (copy-paste safe)

```
def _get_email(self):
    """Extract email from profile."""
    profile = self._get_profile()
    if not profile:
        return None
    user = profile.get('user', profile)
    if isinstance(user, dict):
        email = user.get('email')
        if email:
            return email
        inner = user.get('user', {})
        if isinstance(inner, dict):
            return inner.get('email')
    return None
```

Method: TopStepAccount.get_account_stats

```
def get_account_stats(self)
    Get account stats from TopStep.
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **with self.lock**: enters a context manager.

Code (copy-paste safe)

```
def get_account_stats(self):
    """Get account stats from TopStep."""
    with self.lock:

```

Method: MFFUAccount._get_profile

```
def _get_profile(self)
```

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **return** self._fetch_json(f'{self.API_BASE}/getProfile/').

Code (copy-paste safe)

```
def _get_profile(self):
    return self._fetch_json(f'{self.API_BASE}/getProfile/')
```

Method: MFFUAccount.get_account_stats

```
def get_account_stats(self)
```

Get account stats from MFFU profile.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.

Step by step (top-level body)

1. **with** self.lock: enters a context manager.

Code (copy-paste safe)

```
def get_account_stats(self):
    """Get account stats from MFFU profile."""
    with self.lock:
        now = time.time()
        if now - self._stats_last_fetch < 2.0 and self._cached_stats:
            return self._cached_stats

return billing

```

Method: MFFUAccount._scrape_billing_dom

```
def _scrape_billing_dom(self)
```

Scrape billing from the Prop Account Subscriptions table at /billing.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

- **list comprehension** — Builds a list in a single expression (`[f(x) for x in xs]`). Faster than the equivalent for-loop with `append`, and clearer about intent: this is a transform, not a side-effecting loop.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `current = self._js('window.location.href')` or `""`.
2. `if '/billing'` not in `current`: branches conditionally.
3. Assigns `raw = self._js("\n (function() {\n va....`
4. `if` not `raw`: branches conditionally.
5. `try` block with 1 **except** clause.
6. Assigns `billing = []`.
7. `for` `item` in `items`: iterates.
8. Calls `self.logger.info(...)` for its side effect.
9. `return` `billing`.

Code (copy-paste safe)

```
def _scrape_billing_dom(self):
    """Scrape billing from the Prop Account Subscriptions table at /billing."""
    # Navigate to billing page
    current = self._js("window.location.href") or ""

    Get all prop accounts (paginated).
```

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns all_accounts = [].
2. Assigns page = 1.
3. **while** True: loops until the condition is false.
4. **return** all_accounts.

Code (copy-paste safe)

```

def get_all_accounts(self):
    """Get all prop accounts (paginated)."""
    all_accounts = []
    page = 1
    while True:

```

Method: FundedNextCDPAccount.__init__

```
def __init__(self, username=None, debug_port=9222, pair_id='default')
```

Why these Python concepts were used

- **__init__** — The constructor. Runs after Python has allocated the instance; assigns starting attribute values to self.

Step by step (top-level body)

1. Calls `super().__init__(...)` for its side effect.
2. Assigns `self.username = username or ""`.

Code (copy-paste safe)

```
def __init__(self, username=None, debug_port=9222, pair_id="default"):
    super().__init__(debug_port=debug_port, pair_id=pair_id)
    self.username = username or ""
```

Method: FundedNextCDPAccount._get_token

```
def _get_token(self)

    Extract tokenV1 from browser cookies.
```

Step by step (top-level body)

1. **return** `self._js("\n (function() {\n var c = docu....`

Code (copy-paste safe)

```
def _get_token(self):
    """Extract tokenV1 from browser cookies."""
    return self._js("""
        (function() {
            var c = document.cookie.split(';').find(function(c) {
                return c.trim().indexOf('tokenV1=') === 0;
            });
            return c ? decodeURIComponent(c.split('=')[1]) : null;
        })()
    """)
```

Method: FundedNextCDPAccount._get_email

```
def _get_email(self)

    Get user email from localStorage or fallback to self.username.
```

Step by step (top-level body)

1. **if** `self.username`: branches conditionally.
2. Assigns `email = self._js("\n (function() {\n tr....`
3. **return** `email or ""`.

Code (copy-paste safe)

```
def _get_email(self):
    """Get user email from localStorage or fallback to self.username."""
    if self.username:
        return self.username
```

```

email = self._js("""
    (function() {
        try {
            var u = JSON.parse(localStorage.getItem('user') || '{}');
            return u.email || '';
        } catch(e) { return ''; }
    })()
    """)
return email or ""

```

Method: FundedNextCDPAccount._navigate_to

```
def _navigate_to(self, path)
```

Navigate to a FundedNext page by path.

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `current = self._js('window.location.href')` or `''`.
2. **if** `path` in `current`: branches conditionally.
3. Calls `self._js(...)` for its side effect.
4. Calls `time.sleep(...)` for its side effect.
5. **return** `True`.

Code (copy-paste safe)

```

def _navigate_to(self, path):
    """Navigate to a FundedNext page by path."""
    current = self._js("window.location.href") or ""
    if path in current:
        return True
    self._js(f"window.location.href = 'https://app.fundednext.com{path}'")
    time.sleep(3)
    return True

```

Method: FundedNextCDPAccount._switch_type_tab

```
def _switch_type_tab(self, tab_name='Futures')
```

Click a type tab (Futures / CFDs) via ant-tabs.

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `result = self._js(f"\n (function() {{\n ....`
2. **if** `result == 'clicked'`: branches conditionally.

3. **return** False.

Code (copy-paste safe)

```
def _switch_type_tab(self, tab_name="Futures"):
    """Click a type tab (Futures / CFDs) via ant-tabs."""
    result = self._js(f"""
        (function() {{
            var tabs = document.querySelectorAll('.ant-tabs-tab-btn');
            for (var i = 0; i < tabs.length; i++) {{
                if (tabs[i].textContent.trim() === '{tab_name}') {{
                    tabs[i].click();
                    return 'clicked';
                }}
            }}
            return 'not_found';
        }})()
    """)
    if result == "clicked":
        time.sleep(3)
        return True
    return False
```

Method: FundedNextCDPAccount._switch_status_tab

```
def _switch_status_tab(self, status='Active')
```

Click a status tab (Active/Inactive/Breached).

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `result = self._js(f"\n (function() {{\n ....`
2. `if result == 'clicked':` branches conditionally.
3. **return** False.

Code (copy-paste safe)

```
def _switch_status_tab(self, status="Active"):
    """Click a status tab (Active/Inactive/Breached)."""
    result = self._js(f"""
        (function() {{
            var btns = document.querySelectorAll('.account-wrapper__create-account button');
            for (var i = 0; i < btns.length; i++) {{
                if (btns[i].textContent.trim() === '{status}') {{
                    btns[i].click();
                    return 'clicked';
                }}
            }}
            return 'not_found';
        }})()
    """)
    if result == "clicked":
        time.sleep(2)
        return True
```

```
return False
```

Method: FundedNextCDPAccount._has_accounts

```
def _has_accounts(self)
```

Check if current tab view has accounts.

Step by step (top-level body)

1. **return** not self._js("\n (function() {\n var el =...

Code (copy-paste safe)

```
def _has_accounts(self):
    """Check if current tab view has accounts."""
    return not self._js("""

        })()
    """)
```

Method: FundedNextCDPAccount.get_account_stats

```
def get_account_stats(self)
```

Get FundedNext account stats from the dashboard DOM.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.

Step by step (top-level body)

1. **with** self.lock: enters a context manager.

Code (copy-paste safe)

```
def get_account_stats(self):
    """Get FundedNext account stats from the dashboard DOM."""
    with self.lock:
        now = time.time()

```

Method: FundedNextCDPAccount.get_billing_history

```
def get_billing_history(self)
```

Fetch billing via FundedNext REST API, with DOM scrape fallback.

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns token = self._get_token().
2. if not token: branches conditionally.
3. Assigns email = self._get_email().
4. if not email: branches conditionally.
5. Assigns url = f'{self.API_BASE}/pending-payment-history?email={email}&t...
6. Assigns data = self._fetch_json_bearer(url, token).
7. if not data: branches conditionally.
8. Assigns items = data.get('data', {}).get('data', []) if isinstance(data.g....
9. if not items: branches conditionally.
10. Assigns billing = [].
11. for item in items: iterates.
12. Calls self.logger.info(...) for its side effect.
13. return billing.

    found = shutil.which("chrome") or shutil.which("google-chrome")
    return found

```

```
def _is_chrome_debug_running(port=CDP_DEBUG_PORT)
```

Check if Chrome debug port is already responding.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def _is_chrome_debug_running(port=CDP_DEBUG_PORT):
    """Check if Chrome debug port is already responding."""
    try:
        urllib.request.urlopen(f'http://127.0.0.1:{port}/json/version', timeout=2)
        return True
    except Exception:
        return False
```

```
def ensure_chrome_debug(url=None, port=CDP_DEBUG_PORT)
```

Ensure a Chrome instance with remote debugging is running. If one is already running on the port, just open the URL as a new tab. If not, launch a new Chrome process with the debug port. Returns True if Chrome is available on the port.

Why these Python concepts were used

- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **raise** — Raises an exception explicitly. Either signals an invalid argument the caller should fix, or re-raises after logging.
- **global** — Rebinds a module-level name from inside the function. A smell in larger codebases — usually means a singleton or cache that could be passed in instead.

Step by step (top-level body)

1. Declares globals: `_chrome_process`.
2. **with** `_chrome_lock`: enters a context manager.

Code (copy-paste safe)

```
def ensure_chrome_debug(url=None, port=CDP_DEBUG_PORT):
    """
    Ensure a Chrome instance with remote debugging is running.
    If one is already running on the port, just open the URL as a new tab.
    If not, launch a new Chrome process with the debug port.
    Returns True if Chrome is available on the port.
    """
    global _chrome_process

    with _chrome_lock:

            f'http://127.0.0.1:{port}/json/new?{encoded}',
            method='PUT'
        )
        urllib.request.urlopen(req, timeout=5)
    except Exception:
        try:
            urllib.request.urlopen(
                f'http://127.0.0.1:{port}/json/new?url={url}', timeout=5)
        except Exception:
            pass

def quick_test(debug_port=9222)
```

Test all available prop firm scrapers against open Chrome tabs.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns scrapers = [('Tradeify', TradeifyAccount), ('Lucid Trading', LucidTr....
2. **for** (name, cls) in scrapers: iterates.

Code (copy-paste safe)

```
def quick_test(debug_port=9222):
    """Test all available prop firm scrapers against open Chrome tabs."""
    scrapers = [
        ("Tradeify", TradeifyAccount),
        ("Lucid Trading", LucidTradingAccount),
```

```

        ("TopStep", TopStepAccount),
        ("MFFU", MFFUAccount),
        ("FundedNext", FundedNextCDPAccount),
    ]

    for name, cls in scrapers:
        print(f"\n{'='*60}")
        print(f"  {name}")
        print(f"{'='*60}")
        scraper = cls(debug_port=debug_port)
        try:
            scraper.login()
            print(f"  Connected: {scraper.is_connected()}")

            stats = scraper.get_account_stats()
            print(f"\n  Account Stats:")
            for k, v in stats.items():
                print(f"    {k}: {v}")

            accounts = scraper.get_all_accounts()
            print(f"\n  Accounts: {len(accounts)}")
            for i, acct in enumerate(accounts[:3]):
                acct_name = acct.get('accountName', acct.get('account_number', acct.get('name', f'#{i+1}'))
                print(f"    {acct_name}")

            payouts = scraper.get_payouts()
            print(f"  Payouts: {len(payouts)}")

            billing = scraper.get_billing_history()
            print(f"  Billing records: {len(billing)}")

            scraper.close()
        except ConnectionError as e:
            print(f"  Tab not found — skipping ({e})")
        except Exception as e:
            print(f"  Error: {e}")

```

Step 8.2 — Build trader_companion/fundednext.py

What to do. Create the file trader_companion/fundednext.py in your project root and paste in the code shown in this step. The file is **1386** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from requirements.txt.

What this file is for. FundedNext-specific scraper and account adapter.

trader_companion/fundednext.py

1386 loc · 1 classes · 3 functions · 18 imports

FundedNext-specific scraper and account adapter. It defines **1** class and **3** module-level functions, across **1,386** lines. Module docstring: *FundedNext Dashboard Integration - Selenium Browser*

Module *docstring*

FundedNext Dashboard Integration - Selenium Browser Automation Scrapes account statistics from <https://app.fundednext.com/accounts> Follows the same pattern as TradovateAccount and TopStepXAccount.

Python concepts demonstrated in this module

- Classes and objects
- Comprehensions
- Context managers (with-statements)
- Decorators
- Dunder methods
- Exceptions
- f-strings

Imports — *what each one is for*

```
import os
```

Why imported. Operating-system interface. Path manipulation, environment variables, working-directory operations, exit codes, and thin wrappers around POSIX/Windows syscalls.

Used in this file. `os.environ`, `os.environ.get`, `os.makedirs`, `os.path`, `os.path.exists`, `os.path.join`

Example. `os.path.join(root, 'subdir', 'file.txt')` # joins with the OS-correct separator

Other common scenarios.

- `os.environ.get('API_KEY')` to read environment variables
- `os.makedirs(path, exist_ok=True)` to create nested directories
- `os.listdir(path)` to list a directory's contents
- `os.remove(path)` / `os.rename(src, dst)` to delete or move a file
- `os.getcwd()` / `os.chdir(path)` to inspect or change the working dir

```
import sys
```

Why imported. Access to the running interpreter — `argv`, `stdin/stdout`, exit codes, the import search path, and the platform name.

Used in this file. *No direct attribute access detected — likely imported for side effects, re-export, or string references.*

Example. `sys.exit(1)` # terminate the process with a non-zero status

Other common scenarios.

- `sys.argv[1:]` reads the command-line arguments
- `sys.path.insert(0, 'extra')` prepends to the import search path
- `sys.stderr.write(msg)` writes to standard error
- `sys.platform` tells you 'win32', 'linux', or 'darwin'
- `sys.modules` is the global cache of already-imported modules

```
import re
```

Why imported. Regular expressions. Pattern matching, search, replace, and text extraction.

Used in this file. `re.findall`, `re.match`, `re.search`, `re.sub`

Example. `re.search(r'\d{3}-\d{4}', text)` # returns a Match or None

Other common scenarios.

- `re.findall(pattern, text)` for every non-overlapping match
- `re.sub(pattern, repl, text)` to replace occurrences
- `re.compile(...)` to reuse a pattern (faster in a loop)
- Named groups: `r'(?P<year>\d{4})'` lets you do `m.group('year')`

```
import time
```

Why imported. Timestamps and sleep. Lower-level than `datetime` — works in Unix-epoch seconds.

Used in this file. `time.sleep`, `time.time`

Example. `time.sleep(1.5)` # pause this thread for 1.5 seconds

Other common scenarios.

- `time.time()` returns seconds since the epoch
- `time.monotonic()` for measuring elapsed time (never goes backward)
- `time.perf_counter()` for high-precision benchmarking
- `time.strptime` / `time.strftime` mirror the `datetime` versions

```
import threading
```

Why imported. Threads and synchronisation primitives. Used when work is I/O-bound and the GIL is not a bottleneck (the GIL prevents speed-up on CPU-bound work).

Used in this file. `threading.RLock`

Example. `Thread(target=worker, args=(q,), daemon=True).start()`

Other common scenarios.

- Lock / RLock to guard shared state
- Event for one-shot signals between threads
- Queue (from `queue`) for producer/consumer patterns
- `threading.local()` for thread-local storage

```
import logging
```

Why imported. Structured, levelled logging. Replaces `print()` with filterable, formattable output that can route to files, `stderr`, `syslog`, or HTTP endpoints.

Used in this file. `logging.INFO`, `logging.basicConfig`, `logging.getLogger`

Example. `logging.getLogger(__name__).info('connected to %s', host)`

Other common scenarios.

- `.debug()` / `.info()` / `.warning()` / `.error()` / `.exception()`

- `logger.exception()` captures the current traceback automatically
- `logging.basicConfig(level=logging.INFO)` for quick setup
- Handlers and Formatters route logs to files / streams / syslog

`import hashlib`

Why imported. Cryptographic hash functions — SHA-256, MD5, BLAKE2.

Used in this file. `hashlib.md5`

Example. `hashlib.sha256(b'hello').hexdigest()`

Other common scenarios.

- Pass data in chunks via `.update()` to hash large files
- Use `sha256` / `sha512` for integrity; never MD5 or SHA-1 for security
- For password hashing use `bcrypt/argon2`, NOT raw `hashlib`

`import tempfile`

Why imported. Temporary files and directories that clean themselves up.

Used in this file. `tempfile.gettempdir`

Example. with `tempfile.TemporaryDirectory()` as `d`: ...

Other common scenarios.

- `tempfile.NamedTemporaryFile(delete=False)` for a real path on disk
- `tempfile.mkstemp()` returns a low-level (fd, path) pair

`from selenium import webdriver`

Why imported. Browser automation. Drives a real Chrome instance — the fallback for scraping prop-firm dashboards that have no API.

Used in this file. `webdriver`

Example. `driver.get(url); driver.find_element(By.ID, 'login')`

Other common scenarios.

- `WebDriverWait` + `expected_conditions` for reliable waits
- `ChromeOptions().add_argument('--headless=new')`
- `execute_script(js, *args)` reaches into the page for things the DOM API can't express

`from selenium.webdriver.common.by import By`

Why imported. Browser automation. Drives a real Chrome instance — the fallback for scraping prop-firm dashboards that have no API.

Used in this file. `By`

Example. `driver.get(url); driver.find_element(By.ID, 'login')`

Other common scenarios.

- `WebDriverWait` + `expected_conditions` for reliable waits

- `ChromeOptions().add_argument('--headless=new')`
- `execute_script(js, *args)` reaches into the page for things the DOM API can't express

```
from selenium.webdriver.common.keys import Keys
```

Why imported. Browser automation. Drives a real Chrome instance — the fallback for scraping prop-firm dashboards that have no API.

Used in this file. Keys

Example. `driver.get(url); driver.find_element(By.ID, 'login')`

Other common scenarios.

- `WebDriverWait + expected_conditions` for reliable waits
- `ChromeOptions().add_argument('--headless=new')`
- `execute_script(js, *args)` reaches into the page for things the DOM API can't express

```
from selenium.webdriver.support.ui import WebDriverWait
```

Why imported. Browser automation. Drives a real Chrome instance — the fallback for scraping prop-firm dashboards that have no API.

Used in this file. WebDriverWait

Example. `driver.get(url); driver.find_element(By.ID, 'login')`

Other common scenarios.

- `WebDriverWait + expected_conditions` for reliable waits
- `ChromeOptions().add_argument('--headless=new')`
- `execute_script(js, *args)` reaches into the page for things the DOM API can't express

```
from selenium.webdriver.support import expected_conditions as EC
```

Why imported. Browser automation. Drives a real Chrome instance — the fallback for scraping prop-firm dashboards that have no API.

Used in this file. EC

Example. `driver.get(url); driver.find_element(By.ID, 'login')`

Other common scenarios.

- `WebDriverWait + expected_conditions` for reliable waits
- `ChromeOptions().add_argument('--headless=new')`
- `execute_script(js, *args)` reaches into the page for things the DOM API can't express

```
from selenium.webdriver.chrome.options import Options
```

Why imported. Browser automation. Drives a real Chrome instance — the fallback for scraping prop-firm dashboards that have no API.

Used in this file. Options

Example. `driver.get(url); driver.find_element(By.ID, 'login')`

Other common scenarios.

- `WebDriverWait + expected_conditions` for reliable waits
- `ChromeOptions().add_argument('--headless=new')`
- `execute_script(js, *args)` reaches into the page for things the DOM API can't express

```
from selenium.webdriver.chrome.service import Service
```

Why imported. Browser automation. Drives a real Chrome instance — the fallback for scraping prop-firm dashboards that have no API.

Used in this file. *No direct attribute access detected — likely imported for side effects, re-export, or string references.*

Example. `driver.get(url); driver.find_element(By.ID, 'login')`

Other common scenarios.

- `WebDriverWait + expected_conditions` for reliable waits
- `ChromeOptions().add_argument('--headless=new')`
- `execute_script(js, *args)` reaches into the page for things the DOM API can't express

```
from selenium.common.exceptions import TimeoutException
from selenium.common.exceptions import WebDriverException
from selenium.common.exceptions import NoSuchElementException
from selenium.common.exceptions import StaleElementReferenceException
```

Why imported. Browser automation. Drives a real Chrome instance — the fallback for scraping prop-firm dashboards that have no API.

Used in this file. `NoSuchElementException`, `StaleElementReferenceException`, `TimeoutException`

Example. `driver.get(url); driver.find_element(By.ID, 'login')`

Other common scenarios.

- `WebDriverWait + expected_conditions` for reliable waits
- `ChromeOptions().add_argument('--headless=new')`
- `execute_script(js, *args)` reaches into the page for things the DOM API can't express

```
from functools import wraps
```

Why imported. Higher-order helpers — caching, partial application, decorator authoring tools, reducers.

Used in this file. `wraps`

Example. `@lru_cache(maxsize=128) # memoise this pure function`

Other common scenarios.

- `partial(f, x=1)` pre-binds arguments
- `reduce(f, iterable)` folds an iterable to a single value
- `@wraps(fn)` preserves `__name__`/`__doc__` when writing decorators
- `@cached_property` memoises a property per-instance

```
from dotenv import load_dotenv
```

Why imported. python-dotenv — load .env files into os.environ for twelve-factor configuration in development.

Used in this file. load_dotenv

Example. load_dotenv() # call once at process start

Other common scenarios.

- dotenv_values('.env') returns a dict without polluting os.environ
- Use a real secret store in production (vault, AWS SM, etc.)

Classes

```
class FundedNextAccount
```

FundedNext dashboard automation class with Selenium-based web scraping. Reads account statistics from <https://app.fundednext.com/accounts>. Supports two connection modes: 1. attach_to_existing=True -> Connects to an already-open Chrome via remote debugging 2. attach_to_existing=False -> Launches a new Chrome and logs in with credentials Follows the same interface as TradovateAccount and TopStepXAccount: - login() / connect() - get_account_stats() - is_connected() - close() / disconnect()

```
_chrome_instances = {}
```

Code (copy-paste safe)

```
class FundedNextAccount:
    """
    FundedNext dashboard automation class with Selenium-based web scraping.
    Reads account statistics from https://app.fundednext.com/accounts.

    Supports two connection modes:
    1. attach_to_existing=True -> Connects to an already-open Chrome via remote debugging
    2. attach_to_existing=False -> Launches a new Chrome and logs in with credentials

    Follows the same interface as TradovateAccount and TopStepXAccount:
    - login() / connect()

             use_real_profile=False)

```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **raise** — Raises an exception explicitly. Either signals an invalid argument the caller should fix, or re-raises after logging.
- **__init__** — The constructor. Runs after Python has allocated the instance; assigns starting attribute values to self.

Step by step (top-level body)

1. Assigns `self.username = username` or `"`.
2. Assigns `self.password = password` or `"`.
3. Assigns `self.pair_id = pair_id` or `'default'`.
4. Assigns `self.attach_to_existing = attach_to_existing`.
5. Assigns `self.debug_port = debug_port`.
6. Assigns `self.use_real_profile = use_real_profile`.
7. Assigns `self.logged_in = False`.
8. Assigns `self.driver = None`.
9. Assigns `self._placing_order = False`.

Method: FundedNextAccount.login

```
def login(self, max_retries=3)
```

Login to FundedNext platform

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to `sum`, `any`, `all`, or `max` where the intermediate list would be wasted.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **with self.lock**: enters a context manager.

Code (copy-paste safe)

```

def login(self, max_retries=3):
    """Login to FundedNext platform"""
    with self.lock:
        # If attached to existing session, just verify we're on FundedNext
        if self.attach_to_existing and self.driver:
            try:
                current_url = self.driver.current_url
                if "fundednext.com" in current_url:
                    self.logged_in = True

    self.logger.error(f"[NAV] Selenium fallback also failed: {e2}")
return False

```

Method: FundedNextAccount.switch_status_tab

```
def switch_status_tab(self, status='Active')
```

Switch between Active/Inactive/Breached status tabs. These are buttons inside .account-wrapper__create-account with Tailwind classes.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

def switch_status_tab(self, status="Active"):
    """
    Switch between Active/Inactive/Breached status tabs.
    These are buttons inside .account-wrapper__create-account with Tailwind classes.
    """
    try:
        buttons = self.driver.find_elements(
            By.CSS_SELECTOR, ".account-wrapper__create-account button")
        for btn in buttons:
            if btn.text.strip() == status:
                btn.click()
                time.sleep(2)
                self.logger.info(f"[NAV] Switched to status tab: {status}")
                return True
        self.logger.warning(f"[NAV] Status tab '{status}' not found")
        return False
    except Exception as e:
        self.logger.error(f"[NAV] Failed to switch status tab: {e}")
        return False

```

Method: FundedNextAccount.has_accounts

```
def has_accounts(self)
```

Check if the current tab view has any accounts. FundedNext shows .no-account-wrapper when empty.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def has_accounts(self):
    """
    Check if the current tab view has any accounts.
    FundedNext shows .no-account-wrapper when empty.
    """
    try:
        no_acct = self.driver.find_elements(By.CSS_SELECTOR, ".no-account-wrapper")
        if no_acct and no_acct[0].is_displayed():
            return False
        return True
    except Exception:
        return False
```

Method: FundedNextAccount.is_connected

```
def is_connected(self)

    Check if connected to FundedNext
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def is_connected(self):
    """Check if connected to FundedNext"""
    try:
        if not self.driver:
            return False
        current_url = self.driver.current_url
        return "fundednext.com" in current_url
    except Exception:
        return False
```

Method: FundedNextAccount.get_account_stats

```
@retry_on_stale_element(max_retries=3, delay=1)
def get_account_stats(self)
```

Get FundedNext account statistics from the dashboard. Returns dict with same keys as Tradovate/TopStepX for GUI compatibility: Account Number, Balance, Profit/Loss, Open Trades, Symbol, Direction Plus FundedNext-specific fields: Equity, Drawdown, Profit Target, Phase, Status

Why these Python concepts were used

- **@retry_on_stale_element** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **if** not self.lock.acquire(blocking=False): branches conditionally.
2. **try** block with 1 **except** clause, plus a **finally**.

Code (copy-paste safe)

```
def get_account_stats(self):
    """
    Get FundedNext account statistics from the dashboard.
    Returns dict with same keys as Tradovate/TopStepX for GUI compatibility:
    Account Number, Balance, Profit/Loss, Open Trades, Symbol, Direction
    Plus FundedNext-specific fields:
    Equity, Drawdown, Profit Target, Phase, Status
    """

```

Method: FundedNextAccount.get_all_accounts

```
def get_all_accounts(self)
```

Get statistics for ALL accounts listed on the FundedNext accounts page. Checks both Futures and CFDs tabs (Futures first), Active status. Returns a list of dicts, one per account.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **if** not self.is_connected(): branches conditionally.
2. **with** self.lock: enters a context manager.

Code (copy-paste safe)

```
def get_all_accounts(self):
    """
    Get statistics for ALL accounts listed on the FundedNext accounts page.
    Checks both Futures and CFDs tabs (Futures first), Active status.
    Returns a list of dicts, one per account.
    """

```

Method: FundedNextAccount.get_page_snapshot

```
def get_page_snapshot(self)
```

Debug helper: Get a text snapshot of the current page content. Useful for discovering DOM structure and available selectors.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression ([f(x) for x in xs]). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

def get_page_snapshot(self):

```

Method: FundedNextAccount.get_billing_via_api

```
def get_billing_via_api(self)
```

Fetch billing history via the FundedNext REST API instead of DOM scraping. Returns the same format as `get_billing_history()` but with richer data including the 'login' field (FundedNext internal account ID). API: `GET /api/v1/pending-payment-history?email=...&type=1&page=1&limit=20` Requires Bearer token from the `tokenV1` cookie.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't

have to handle it.

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Imports json (lazy import inside the function).

    return mapping

```

Method: FundedNextAccount.get_account_overview

```
def get_account_overview(self, account_id)
```

Get detailed account overview via the FundedNext API. API: GET /api/v1/account-overview?account_id={account_id} Returns dict with account_details (breached, breached_by, login, account_name, type, etc.), stats (balance, profit, win_rate), objectives, and breach_event_details. Returns None on failure.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Imports json (lazy import inside the function).
2. try block with 1 **except** clause.

Code (copy-paste safe)

```

def get_account_overview(self, account_id):
    """
    Get detailed account overview via the FundedNext API.

    API: GET /api/v1/account-overview?account_id={account_id}

    Returns dict with account_details (breached, breached_by, login, account_name, type, etc.),
    stats (balance, profit, win_rate), objectives, and breach_event_details.
    Returns None on failure.
    """
    import json as _json
    try:
        token = self.driver.execute_script("""
            var c = document.cookie.split(';').find(function(c) {
                return c.trim().indexOf('tokenV1=') === 0;
            });
            return c ? decodeURIComponent(c.split('=')[1]) : null;
        """)
        if not token:
            self.logger.warning("[OVERVIEW] No tokenV1 cookie found")
            return None

        result = self.driver.execute_cdp_cmd("Runtime.evaluate", {
            "expression": f"""

```

```

        (async function() {{
            try {{
                var resp = await fetch(
                    'https://api.fundednext.com/api/v1/account-overview?account_id={account_id}',
                    {{headers: {{'Authorization': 'Bearer {token}',
                        'Accept': 'application/json'}}}}
                );
                return await resp.text();
            }} catch(e) {{
                return JSON.stringify({{error: e.toString()}});
            }}
        }})()
        """

        f"breached_by={acct_details.get('breached_by')}")

    return overview

except Exception as e:
    self.logger.error(f"[OVERVIEW] Failed for account_id={account_id}: {e}")
    return None

```

Method: FundedNextAccount.disconnect

```

def disconnect(self)
    Disconnect from FundedNext

```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `self.logged_in = False`.
2. `if self.driver:` branches conditionally.
3. Assigns `instance_key = f'fundednext_{self.username}_{self.pair_id}'`.
4. Calls `self._chrome_instances.pop(...)` for its side effect.

Code (copy-paste safe)

```
def disconnect(self):
    """Disconnect from FundedNext"""
    self.logged_in = False
    if self.driver:
        try:
            # If attached to existing Chrome, don't quit - just detach
            if self.attach_to_existing:
                self.logger.info("[DISCONNECT] Detaching from existing Chrome (not closing)")
                self.driver = None
            else:
                self.logger.info("[DISCONNECT] Closing Chrome instance")
                self.driver.quit()
                self.driver = None
        except Exception as e:
            self.logger.warning(f"[DISCONNECT] Error: {e}")
            self.driver = None

    # Remove from registry
    instance_key = f"fundednext_{self.username}_{self.pair_id}"
    self._chrome_instances.pop(instance_key, None)
```

Method: `FundedNextAccount.close`

```
def close(self)
    Close connection - alias for disconnect()
```

Step by step (top-level body)

1. Calls `self.disconnect(...)` for its side effect.

Code (copy-paste safe)

```
def close(self):
    """Close connection - alias for disconnect()"""
    self.disconnect()
```

Functions

```
def retry_on_stale_element(max_retries=3, delay=1)
```

Decorator to retry web operations that may fail due to stale elements

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **raise** — Raises an exception explicitly. Either signals an invalid argument the caller should fix, or re-raises after logging.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.

Step by step (top-level body)

1. Defines a nested function decorator(...).
2. **return** decorator.

Code (copy-paste safe)

```
def retry_on_stale_element(max_retries=3, delay=1):
    """Decorator to retry web operations that may fail due to stale elements"""
    def decorator(func):
        @wraps(func)
        def wrapper(self, *args, **kwargs):
            for attempt in range(max_retries):
                try:
                    return func(self, *args, **kwargs)
                except (StaleElementReferenceException, NoSuchElementException) as e:
                    if attempt == max_retries - 1:
                        self.logger.error(f"Max retries reached for {func.__name__}: {e}")
                        raise e
                    self.logger.warning(
                        f"Retrying {func.__name__} due to stale element (attempt {attempt + 1})")
                    time.sleep(delay)
            return None
        return wrapper
    return decorator
```

```
def cdp_scrape(debug_port=9222)
```

Scrape FundedNext data via Chrome DevTools Protocol directly. Requires Chrome running with --remote-debugging-port=<port>. Falls back to Selenium if CDP connection fails.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Imports urllib.request (lazy import inside the function).
2. Imports json (lazy import inside the function).

3. try block with 1 except clause.

Code (copy-paste safe)

```
def cdp_scrape(debug_port=9222):
    """
    Scrape FundedNext data via Chrome DevTools Protocol directly.
    Requires Chrome running with --remote-debugging-port=<port>.
    Falls back to Selenium if CDP connection fails.
    """
    import urllib.request
    import json

    try:
        data = urllib.request.urlopen(f'http://127.0.0.1:{debug_port}/json', timeout=5).read()
        tabs = json.loads(data)
        fn_tab = next((t for t in tabs if 'fundednext' in t.get('url', '')), None)

        if not fn_tab:
            print("FundedNext tab not found. Tabs available:")
            for t in tabs:
                if t.get('type') == 'page':
                    print(f" {t['title']}: {t['url'][:80]}")
            return None

        import websocket
        ws = websocket.create_connection(fn_tab['webSocketDebuggerUrl'], timeout=10)

        # Get full page text
        ws.send(json.dumps({'id': 1, 'method': 'Runtime.evaluate',
                           'params': {'expression': 'document.body.innerText', 'returnByValue': True}}))
        body_text = json.loads(ws.recv())['result']['result']['value']

        # Get dollar values
        ws.send(json.dumps({'id': 2, 'method': 'Runtime.evaluate',
                           'params': {
                               'expression': '(document.body.innerText.match(/-?\\$[\\d,]+\\.?\\$\\s?/))',
                               'returnByValue': True}}))
        dollars = json.loads(ws.recv())['result']['result']['value']

        # Get card elements
        js_cards = '''(function() => {
            const cards = document.querySelectorAll(
                '[class*="card"]', [class*="Card"], [class*="account"], [class*="Account"]);
            const r = []; cards.forEach((c, i) => {
                if(c.innerText.trim().length > 20) r.push({i: i, cls: c.className.substring(0,200),
                    text: c.innerText.substring(0,600)});
            }); return JSON.stringify(r.slice(0, 15));
        })()'''
        ws.send(json.dumps({'id': 3, 'method': 'Runtime.evaluate',
                           'params': {'expression': js_cards, 'returnByValue': True}}))
        cards = json.loads(json.loads(ws.recv())['result']['result']['value'])

        ws.close()

        return {'url': fn_tab['url'], 'title': fn_tab['title'],
                'body_text': body_text, 'dollars': dollars, 'cards': cards}
    except Exception as e:
        print(f"CDP scrape failed: {e}")
        return None
```

```
def quick_test(debug_port=9222, mode='auto')
```

Quick test: Try CDP-direct first, then fall back to Selenium with fresh Chrome. mode: "cdp" = CDP only, "selenium" = Selenium only, "auto" = try both

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.

Step by step (top-level body)

1. Imports time (lazy import inside the function).
2. **if** mode in ('auto', 'cdp'): branches conditionally.
3. Calls print(...) for its side effect.
4. Calls print(...) for its side effect.
5. Assigns fn = FundedNextAccount(attach_to_existing=False, use_real_prof....
6. Calls fn.driver.get(...) for its side effect.
7. Calls time_mod.sleep(...) for its side effect.
8. Assigns current_url = fn.driver.current_url.
9. Calls print(...) for its side effect.
10. **if** 'fundednext.com/accounts' in current_url: branches conditionally (with an **else/elif** arm).
11. Calls print(...) for its side effect.
12. Calls print(...) for its side effect.
13. Assigns snapshot = fn.get_page_snapshot().
14. **if** isinstance(snapshot, dict): branches conditionally (with an **else/elif** arm).
15. ... and 7 more statement(s) in the body.

Code (copy-paste safe)

```
def quick_test(debug_port=9222, mode="auto"):

return fn

```

Step 8.3 — Build trader_companion/topstepx.py

What to do. Create the file trader_companion/topstepx.py in your project root and paste in the code shown in this step. The file is **4420** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from requirements.txt.

What this file is for. TopstepX-specific scraper and account adapter.

trader_companion/topstepx.py

4420 loc · 1 classes · 3 functions · 24 imports

TopstepX-specific scraper and account adapter. It defines **1** class and **3** module-level functions, across **4,420** lines. Module docstring: *TopStepX Trading Platform Integration - MFFU Blueprint Compatible*

Module docstring

TopStepX Trading Platform Integration - MFFU Blueprint Compatible Handles connection and trading operations with TopStepX platform using MFFU blueprint structure

Python concepts demonstrated in this module

• Classes and objects • Comprehensions • Context managers (with-statements) • Decorators • Dunder methods • Exceptions • f-strings • Properties

Imports — what each one is for

```
import os
```

Why imported. Operating-system interface. Path manipulation, environment variables, working-directory operations, exit codes, and thin wrappers around POSIX/Windows syscalls.

Used in this file. os.getenv, os.path, os.path.dirname, os.path.join

Example. os.path.join(root, 'subdir', 'file.txt') # joins with the OS-correct separator

Other common scenarios.

- os.environ.get('API_KEY') to read environment variables
- os.makedirs(path, exist_ok=True) to create nested directories
- os.listdir(path) to list a directory's contents
- os.remove(path) / os.rename(src, dst) to delete or move a file
- os.getcwd() / os.chdir(path) to inspect or change the working dir

```
import sys
```

Why imported. Access to the running interpreter — argv, stdin/stdout, exit codes, the import search path, and the platform name.

Used in this file. `sys.path`, `sys.path.insert`

Example. `sys.exit(1)` # terminate the process with a non-zero status

Other common scenarios.

- `sys.argv[1:]` reads the command-line arguments
- `sys.path.insert(0, 'extra')` prepends to the import search path
- `sys.stderr.write(msg)` writes to standard error
- `sys.platform` tells you 'win32', 'linux', or 'darwin'
- `sys.modules` is the global cache of already-imported modules

`import time`

Why imported. Timestamps and sleep. Lower-level than `datetime` — works in Unix-epoch seconds.

Used in this file. `time.sleep`, `time.time`

Example. `time.sleep(1.5)` # pause this thread for 1.5 seconds

Other common scenarios.

- `time.time()` returns seconds since the epoch
- `time.monotonic()` for measuring elapsed time (never goes backward)
- `time.perf_counter()` for high-precision benchmarking
- `time.strftime` / `time.strptime` mirror the `datetime` versions

`import threading`

Why imported. Threads and synchronisation primitives. Used when work is I/O-bound and the GIL is not a bottleneck (the GIL prevents speed-up on CPU-bound work).

Used in this file. `threading.RLock`, `threading.Thread`

Example. `Thread(target=worker, args=(q,), daemon=True).start()`

Other common scenarios.

- Lock / RLock to guard shared state
- Event for one-shot signals between threads
- Queue (from `queue`) for producer/consumer patterns
- `threading.local()` for thread-local storage

`import logging`

Why imported. Structured, levelled logging. Replaces `print()` with filterable, formattable output that can route to files, `stderr`, `syslog`, or HTTP endpoints.

Used in this file. `logging.INFO`, `logging.basicConfig`, `logging.error`, `logging.getLogger`, `logging.info`, `logging.warning`

Example. `logging.getLogger(__name__).info('connected to %s', host)`

Other common scenarios.

- `.debug()` / `.info()` / `.warning()` / `.error()` / `.exception()`

- `logger.exception()` captures the current traceback automatically
- `logging.basicConfig(level=logging.INFO)` for quick setup
- Handlers and Formatters route logs to files / streams / syslog

`import random`

Why imported. Pseudo-random numbers — fine for jitter, sampling, shuffling. NEVER for security; use secrets for that.

Used in this file. *No direct attribute access detected — likely imported for side effects, re-export, or string references.*

Example. `random.uniform(0.5, 1.5)` # backoff jitter

Other common scenarios.

- `random.choice(seq)` picks one item
- `random.shuffle(list)` rearranges in place
- `random.seed(n)` makes the sequence reproducible
- `random.sample(seq, k)` draws k unique items

`import hashlib`

Why imported. Cryptographic hash functions — SHA-256, MD5, BLAKE2.

Used in this file. `hashlib.md5`

Example. `hashlib.sha256(b'hello').hexdigest()`

Other common scenarios.

- Pass data in chunks via `.update()` to hash large files
- Use sha256 / sha512 for integrity; never MD5 or SHA-1 for security
- For password hashing use `bcrypt/argon2`, NOT raw `hashlib`

`import tempfile`

Why imported. Temporary files and directories that clean themselves up.

Used in this file. `tempfile.gettempdir`

Example. `with tempfile.TemporaryDirectory() as d: ...`

Other common scenarios.

- `tempfile.NamedTemporaryFile(delete=False)` for a real path on disk
- `tempfile.mkstemp()` returns a low-level (fd, path) pair

`from selenium import webdriver`

Why imported. Browser automation. Drives a real Chrome instance — the fallback for scraping prop-firm dashboards that have no API.

Used in this file. `webdriver`

Example. `driver.get(url); driver.find_element(By.ID, 'login')`

Other common scenarios.

- `WebDriverWait + expected_conditions` for reliable waits
- `ChromeOptions().add_argument('--headless=new')`
- `execute_script(js, *args)` reaches into the page for things the DOM API can't express

```
from selenium.webdriver.common.by import By
```

Why imported. Browser automation. Drives a real Chrome instance — the fallback for scraping prop-firm dashboards that have no API.

Used in this file. By

Example. `driver.get(url); driver.find_element(By.ID, 'login')`

Other common scenarios.

- `WebDriverWait + expected_conditions` for reliable waits
- `ChromeOptions().add_argument('--headless=new')`
- `execute_script(js, *args)` reaches into the page for things the DOM API can't express

```
from selenium.webdriver.common.keys import Keys
```

Why imported. Browser automation. Drives a real Chrome instance — the fallback for scraping prop-firm dashboards that have no API.

Used in this file. Keys

Example. `driver.get(url); driver.find_element(By.ID, 'login')`

Other common scenarios.

- `WebDriverWait + expected_conditions` for reliable waits
- `ChromeOptions().add_argument('--headless=new')`
- `execute_script(js, *args)` reaches into the page for things the DOM API can't express

```
from selenium.webdriver.common.action_chains import ActionChains
```

Why imported. Browser automation. Drives a real Chrome instance — the fallback for scraping prop-firm dashboards that have no API.

Used in this file. ActionChains

Example. `driver.get(url); driver.find_element(By.ID, 'login')`

Other common scenarios.

- `WebDriverWait + expected_conditions` for reliable waits
- `ChromeOptions().add_argument('--headless=new')`
- `execute_script(js, *args)` reaches into the page for things the DOM API can't express

```
from selenium.webdriver.support.ui import WebDriverWait
```

Why imported. Browser automation. Drives a real Chrome instance — the fallback for scraping prop-firm dashboards that have no API.

Used in this file. WebDriverWait

Example. driver.get(url); driver.find_element(By.ID, 'login')

Other common scenarios.

- WebDriverWait + expected_conditions for reliable waits
- ChromeOptions().add_argument('--headless=new')
- execute_script(js, *args) reaches into the page for things the DOM API can't express

```
from selenium.webdriver.support import expected_conditions as EC
```

Why imported. Browser automation. Drives a real Chrome instance — the fallback for scraping prop-firm dashboards that have no API.

Used in this file. EC

Example. driver.get(url); driver.find_element(By.ID, 'login')

Other common scenarios.

- WebDriverWait + expected_conditions for reliable waits
- ChromeOptions().add_argument('--headless=new')
- execute_script(js, *args) reaches into the page for things the DOM API can't express

```
from selenium.webdriver.common.action_chains import ActionChains
```

Why imported. Browser automation. Drives a real Chrome instance — the fallback for scraping prop-firm dashboards that have no API.

Used in this file. ActionChains

Example. driver.get(url); driver.find_element(By.ID, 'login')

Other common scenarios.

- WebDriverWait + expected_conditions for reliable waits
- ChromeOptions().add_argument('--headless=new')
- execute_script(js, *args) reaches into the page for things the DOM API can't express

```
from selenium.webdriver.chrome.options import Options
```

Why imported. Browser automation. Drives a real Chrome instance — the fallback for scraping prop-firm dashboards that have no API.

Used in this file. Options

Example. driver.get(url); driver.find_element(By.ID, 'login')

Other common scenarios.

- WebDriverWait + expected_conditions for reliable waits
- ChromeOptions().add_argument('--headless=new')
- execute_script(js, *args) reaches into the page for things the DOM API can't express

```
from selenium.webdriver.chrome.service import Service
```

Why imported. Browser automation. Drives a real Chrome instance — the fallback for scraping prop-firm dashboards that have no API.

Used in this file. *No direct attribute access detected — likely imported for side effects, re-export, or string references.*

Example. `driver.get(url); driver.find_element(By.ID, 'login')`

Other common scenarios.

- `WebDriverWait + expected_conditions` for reliable waits
- `ChromeOptions().add_argument('--headless=new')`
- `execute_script(js, *args)` reaches into the page for things the DOM API can't express

```
from selenium.common.exceptions import TimeoutException
from selenium.common.exceptions import WebDriverException
from selenium.common.exceptions import NoSuchElementException
from selenium.common.exceptions import StaleElementReferenceException
```

Why imported. Browser automation. Drives a real Chrome instance — the fallback for scraping prop-firm dashboards that have no API.

Used in this file. `NoSuchElementException`, `StaleElementReferenceException`, `TimeoutException`

Example. `driver.get(url); driver.find_element(By.ID, 'login')`

Other common scenarios.

- `WebDriverWait + expected_conditions` for reliable waits
- `ChromeOptions().add_argument('--headless=new')`
- `execute_script(js, *args)` reaches into the page for things the DOM API can't express

```
from datetime import datetime
```

Why imported. Dates, times, durations. The fundamental temporal types: `date`, `time`, `datetime`, `timedelta`, `timezone`.

Used in this file. `datetime`

Example. `datetime.now() - timedelta(days=7) # one week ago`

Other common scenarios.

- `datetime.strptime(s, '%Y-%m-%d')` parses a string
- `datetime.strftime(fmt)` formats one
- `datetime.fromtimestamp(n)` converts a Unix epoch
- `datetime.utcnow()` for UTC (better: `datetime.now(timezone.utc)`)

```
from functools import wraps
```

Why imported. Higher-order helpers — caching, partial application, decorator authoring tools, reducers.

Used in this file. `wraps`

Example. `@lru_cache(maxsize=128) # memoise this pure function`

Other common scenarios.

- `partial(f, x=1)` pre-binds arguments
- `reduce(f, iterable)` folds an iterable to a single value
- `@wraps(fn)` preserves `__name__`/`__doc__` when writing decorators
- `@cached_property` memoises a property per-instance

```
from dotenv import load_dotenv
```

Why imported. `python-dotenv` — load `.env` files into `os.environ` for twelve-factor configuration in development.

Used in this file. `load_dotenv`

Example. `load_dotenv()` # call once at process start

Other common scenarios.

- `dotenv_values('.env')` returns a dict without polluting `os.environ`
- Use a real secret store in production (vault, AWS SM, etc.)

```
import requests
```

Why imported. The de-facto Python HTTP client. Synchronous; trades raw speed for an extremely friendly API.

Used in this file. `requests.Session`

Example. `requests.get(url, timeout=10).json()`

Other common scenarios.

- `Session()` reuses TCP connections across calls
- `params=`, `headers=`, `json=`, `data=` for query/body shapes
- `raise_for_status()` turns 4xx/5xx into an exception
- `stream=True` for large downloads

```
import base64
```

Why imported. `base64` — module specific to this codebase. See the chapter that covers its source for the full definition.

Used in this file. `base64.urlsafe_b64decode`

```
import json
```

Why imported. JSON encoding and decoding — the standard wire format for config files, API payloads, and inter-process messages.

Used in this file. `json.loads`

Example. `json.loads(response.text)` # parse a JSON string to dict

Other common scenarios.

- `json.dumps(obj, indent=2)` for pretty-printing

- `json.dump(obj, file)` / `json.load(file)` for file I/O
- `default=str` handles non-serialisable types like `datetime`
- `object_hook=` customises decoding (e.g., to `dataclass` instances)

Module constants

Each line below is followed by a plain-English note explaining what it does and why it is written that way.

```
DEFAULT_SYMBOL = os.getenv('TOPSTEPX_SYMBOL') or 'MNQM25'
```

Module-level constant — bound once at import time and referenced from the functions and classes below.

```
DEFAULT_TP = os.getenv('TOPSTEPX_TAKEPROFIT_TICKS')
```

Reads `TOPSTEPX_TAKEPROFIT_TICKS` from the environment. Returns `None` if unset.

```
DEFAULT_SL = os.getenv('TOPSTEPX_STOPLOSS_TICKS')
```

Reads `TOPSTEPX_STOPLOSS_TICKS` from the environment. Returns `None` if unset.

Classes

```
class TopStepXAccount
```

TopStepX trading automation class with robust Selenium-based web automation. Handles login, symbol selection, order placement, and account statistics. Ensures single Chrome instance per account to prevent resource conflicts. Follows MFFU blueprint pattern for consistency.

```
_chrome_instances = {}
```

Code (copy-paste safe)

```
class TopStepXAccount:
    """
    TopStepX trading automation class with robust Selenium-based web automation.
    Handles login, symbol selection, order placement, and account statistics.
    Ensures single Chrome instance per account to prevent resource conflicts.
    Follows MFFU blueprint pattern for consistency.

```

Get the path to ChromeDriver executable with auto-compatibility check

Step by step (top-level body)

1. Calls `logging.info(...)` for its side effect.

2. `return None`.

Code (copy-paste safe)

```
def _get_chromedriver_path(self):
    """Get the path to ChromeDriver executable with auto-compatibility check"""
    # SELENIUM 4.15+ AUTO-MANAGEMENT: Let Selenium Manager handle ChromeDriver automatically
    # This ensures ChromeDriver always matches the installed Chrome version
    logging.info("[AUTO] Using Selenium Manager for automatic ChromeDriver version matching")
    return None
```

Method: `TopStepXAccount._ensure_chrome_compatibility`

```
def _ensure_chrome_compatibility(self)
    Ensure Chrome-ChromeDriver version compatibility
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. `try` block with 1 `except` clause.

Code (copy-paste safe)

```
def _ensure_chrome_compatibility(self):
    """Ensure Chrome-ChromeDriver version compatibility"""
    try:
        # Import the compatibility manager
        sys.path.insert(0, os.path.dirname(os.path.dirname(__file__)))
        from chrome_auto_compatibility import ChromeVersionManager # type: ignore

        manager = ChromeVersionManager()
        success = manager.ensure_compatibility()

        if success:
            logging.info("[CHECK] Chrome-ChromeDriver compatibility verified")

```

Method: TopStepXAccount.login

```
def login(self, max_retries=3)
```

Login to TopStepX platform

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **generator expression** — Uses a generator expression (parentheses, not square brackets) — the items are produced lazily. Common as the argument to sum, any, all, or max where the intermediate list would be wasted.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **raise** — Raises an exception explicitly. Either signals an invalid argument the caller should fix, or re-raises after logging.

Step by step (top-level body)

1. **with self.lock**: enters a context manager.

Code (copy-paste safe)

```

def login(self, max_retries=3):
    """
    Login to TopStepX platform
    """
    # Acquire lock to prevent stats fetching during login
    with self.lock:
        if not self.username or not self.password:
            self.logger.error("Username and password are required for TopStepX login")
            return False

    Returns (is_valid, message)
    """
    if not self.username:
        return False, "Username is required"
    if not self.password:
        return False, "Password is required"
    return True, "Credentials are valid"
```

Method: TopStepXAccount._extract_api_token

```
def _extract_api_token(self)

    Extract JWT token from browser localStorage after login
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code [\(copy-paste safe\)](#)

```
def _extract_api_token(self):
    """Extract JWT token from browser localStorage after login"""
    try:
        if not self.driver:
            return False
        token = self.driver.execute_script("return localStorage.getItem('token')")
        if not token or len(token) < 50:
            self.logger.warning("[API] No JWT token found in localStorage")
            return False
        self._api_token = token
        # Decode JWT claims to get userId and expiry
        parts = token.split(".")
        if len(parts) >= 2:
            payload = parts[1] + "=" * (4 - len(parts[1]) % 4)
            try:
                claims = json.loads(base64.urlsafe_b64decode(payload))
                self._api_user_id = claims.get(
                    "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/nameidentifier"
                )

        if resp.status_code == 200:
            ct = resp.headers.get("content-type", "")
            if "json" in ct or resp.text.strip().startswith(("{", "[")):
                return resp.json()
            return resp.text
        elif resp.status_code == 204:
            return [] # No content
        else:
            self.logger.warning(f"[API] GET {path} returned {resp.status_code}")
            return None
    except Exception as e:
```

```
self.logger.error(f"[API] GET {path} failed: {e}")
return None
```

Method: TopStepXAccount._api_post

```
def _api_post(self, path, data=None, base_url=None)
```

Make authenticated POST request to TopStepX API. Returns parsed JSON or None.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **if** not self._api_session: branches conditionally.
2. Calls self._refresh_api_token(...) for its side effect.
3. Assigns url = f'{base_url or self.user_api_url}{path}'.
4. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def _api_post(self, path, data=None, base_url=None):
    """Make authenticated POST request to TopStepX API. Returns parsed JSON or None."""
    if not self._api_session:
        if not self._extract_api_token():
            return None
    self._refresh_api_token()
    url = f'{base_url or self.user_api_url}{path}'
    try:
        resp = self._api_session.post(url, json=data, timeout=10)
        if resp.status_code in (200, 201):
            ct = resp.headers.get("content-type", "")
            if "json" in ct or resp.text.strip().startswith(("{", "[")):
                return resp.json()
            return resp.text
        elif resp.status_code == 204:
            return []
        else:
            self.logger.warning(f"[API] POST {path} returned {resp.status_code}")
            return None
    except Exception as e:
        self.logger.error(f"[API] POST {path} failed: {e}")
        return None
```

Method: TopStepXAccount.api_available

```
@property
def api_available(self)
```

Check if REST API is available (token extracted and session ready)

Why these Python concepts were used

- **@property** — Wrapped in **@property** so callers access the value with attribute syntax (`obj.x`) instead of a method call. Lets the implementation compute or validate the value lazily without changing the call site.

Step by step (top-level body)

1. **return** `self._api_session` is not `None` and `self._api_token` is not `None`.

Code (copy-paste safe)

```
def api_available(self):
    """Check if REST API is available (token extracted and session ready)"""
    return self._api_session is not None and self._api_token is not None
```

Method: `TopStepXAccount.api_get_user`

```
def api_get_user(self)
```

Get user profile via REST API. Returns dict with: `userName`, `email`, `userId`, `firstName`, `lastName`, `has2FA`, etc.

Step by step (top-level body)

1. **return** `self._api_get('/User')`.

Code (copy-paste safe)

```
def api_get_user(self):
    """Get user profile via REST API.
    Returns dict with: userName, email, userId, firstName, lastName, has2FA, etc."""
    return self._api_get("/User")
```

Method: `TopStepXAccount.api_get_trading_accounts`

```
def api_get_trading_accounts(self)
```

Get all trading accounts via REST API. Returns list of account dicts with: `accountId`, `accountName`, `balance`, `startingBalance`, `profitAndLoss`, `winRate`, `totalTrades`, `status`, `realizedDayPnl`, `openPnl`, `highestBalance`, `maximumLoss`, etc.

Step by step (top-level body)

1. **return** `self._api_get('/TradingAccount')`.

Code (copy-paste safe)

```
def api_get_trading_accounts(self):
    """Get all trading accounts via REST API.
    Returns list of account dicts with: accountId, accountName, balance,
    startingBalance, profitAndLoss, winRate, totalTrades, status,
    realizedDayPnl, openPnl, highestBalance, maximumLoss, etc."""
    return self._api_get("/TradingAccount")
```

Method: `TopStepXAccount.api_get_positions`

```
def api_get_positions(self, user_id=None)
```

Get all open positions via REST API. Returns list of position dicts.

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. Assigns `uid = user_id` or `self._api_user_id`.
2. `if not uid`: branches conditionally.
3. `return self._api_get(f'/Position/all/user/{uid}')` or `[]`.

Code (copy-paste safe)

```
def api_get_positions(self, user_id=None):
    """Get all open positions via REST API.
    Returns list of position dicts."""
    uid = user_id or self._api_user_id
    if not uid:
        self.logger.warning("[API] No user_id available for positions query")
        return []
    return self._api_get(f"/Position/all/user/{uid}") or []
```

Method: TopStepXAccount.api_get_orders

```
def api_get_orders(self, account_id=None)
```

Get pending orders via REST API. Returns list of order dicts.

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.

Step by step (top-level body)

1. Assigns `acct_id = account_id` or `self._api_account_id`.
2. `if not acct_id`: branches conditionally.
3. `if not acct_id`: branches conditionally.
4. `return self._api_get(f'/Order?accountId={acct_id}')` or `[]`.

Code (copy-paste safe)

```
def api_get_orders(self, account_id=None):
    """Get pending orders via REST API.
    Returns list of order dicts."""
    acct_id = account_id or self._api_account_id
    if not acct_id:
        # Try to get from trading accounts
        accounts = self.api_get_trading_accounts()
        if accounts and isinstance(accounts, list) and len(accounts) > 0:
            acct_id = accounts[0].get("accountId")
            self._api_account_id = acct_id
```

```

    if not acct_id:
        return []
    return self._api_get(f"/Order?accountId={acct_id}") or []

```

Method: TopStepXAccount.api_get_trades

```
def api_get_trades(self, account_id=None)
```

Get trade history via REST API. Returns list of trade dicts with: id, symbolId, contractId, accountId, entryPrice, exitPrice, fees, pnl, positionSize, tradeDuration, etc.

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.

Step by step (top-level body)

1. Assigns `acct_id = account_id` or `self._api_account_id`.
2. `if not acct_id`: branches conditionally.
3. `if not acct_id`: branches conditionally.
4. `return self._api_get(f"/Trade/id/{acct_id}")` or `[]`.

Code (copy-paste safe)

```

def api_get_trades(self, account_id=None):
    """Get trade history via REST API.
    Returns list of trade dicts with: id, symbolId, contractId, accountId,
    entryPrice, exitPrice, fees, pnl, positionSize, tradeDuration, etc."""
    acct_id = account_id or self._api_account_id
    if not acct_id:
        accounts = self.api_get_trading_accounts()
        if accounts and isinstance(accounts, list) and len(accounts) > 0:
            acct_id = accounts[0].get("accountId")
            self._api_account_id = acct_id
    if not acct_id:
        return []
    return self._api_get(f"/Trade/id/{acct_id}") or []

```

Method: TopStepXAccount.api_get_contracts

```
def api_get_contracts(self)
```

Get all active tradeable contracts via REST API. Returns list with: productId, productName, contractId, contractName, tickValue, tickSize, pointValue, fees, exchange, expiration, etc.

Step by step (top-level body)

1. `return self._api_get('/UserContract/active/nonprofesional')` or `[]`.

Code (copy-paste safe)

```

def api_get_contracts(self):
    """Get all active tradeable contracts via REST API.
    Returns list with: productId, productName, contractId, contractName,

```

```
tickValue, tickSize, pointValue, fees, exchange, expiration, etc."""
return self._api_get("/UserContract/active/nonprofesional") or []
```

Method: TopStepXAccount.api_get_metadata

```
def api_get_metadata(self)
```

Get symbol metadata via REST API. Returns list with: symbol, friendlyName, fullName, tickSize, tickValue, contractCost, fees, decimalPlaces, exchange, etc.

Step by step (top-level body)

1. **return** self._api_get('/Metadata') or [].

Code (copy-paste safe)

```
def api_get_metadata(self):
    """Get symbol metadata via REST API.
    Returns list with: symbol, friendlyName, fullName, tickSize, tickValue,
    contractCost, fees, decimalPlaces, exchange, etc."""
    return self._api_get("/Metadata") or []
```

Method: TopStepXAccount.api_get_market_status

```
def api_get_market_status(self)
```

Get market open/close status for all symbols via REST API. Returns list with: symbolId, contractId, status, isOpen, openedAt, etc.

Step by step (top-level body)

1. **return** self._api_get('/MarketStatus/markets') or [].

Code (copy-paste safe)

```
def api_get_market_status(self):
    """Get market open/close status for all symbols via REST API.
    Returns list with: symbolId, contractId, status, isOpen, openedAt, etc."""
    return self._api_get("/MarketStatus/markets") or []
```

Method: TopStepXAccount.api_get_trading_rules

```
def api_get_trading_rules(self)
```

Get trading rules (DAILY_LOSS, MAXIMUM_LOSS, MARGIN_SCALE) via REST API.

Step by step (top-level body)

1. **return** self._api_get('/TradingRule') or [].

Code (copy-paste safe)

```
def api_get_trading_rules(self):
    """Get trading rules (DAILY_LOSS, MAXIMUM_LOSS, MARGIN_SCALE) via REST API."""
    return self._api_get("/TradingRule") or []
```

Method: TopStepXAccount.api_get_template_rules

```
def api_get_template_rules(self, template_id=1)
```

Get account template rules (loss limits, etc.) via REST API.

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **return** `self._api_get(f'/AccountTemplateRule/rules/{template_id}/all')` or `[]`.

Code (copy-paste safe)

```
def api_get_template_rules(self, template_id=1):
    """Get account template rules (loss limits, etc.) via REST API."""
    return self._api_get(f"/AccountTemplateRule/rules/{template_id}/all") or []
```

Method: `TopStepXAccount.api_get_violations`

```
def api_get_violations(self, account_id=None)
```

Get active rule violations via REST API.

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.

Step by step (top-level body)

1. Assigns `acct_id = account_id` or `self._api_account_id`.
2. **if not** `acct_id`: branches conditionally.
3. **if not** `acct_id`: branches conditionally.
4. **return** `self._api_get(f'/Violations/active/{acct_id}')` or `[]`.

Code (copy-paste safe)

```
def api_get_violations(self, account_id=None):
    """Get active rule violations via REST API."""
    acct_id = account_id or self._api_account_id
    if not acct_id:

```

Method: TopStepXAccount.list_accounts

```
def list_accounts(self)
```

List all trading accounts available for this user. Returns list of dicts with: accountId, accountName, balance, status, ineligible, etc. Uses REST API if available, otherwise falls back to reading the UI dropdown.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **if** self.api_available: branches conditionally.
2. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

def list_accounts(self):
    """List all trading accounts available for this user.
    Returns list of dicts with: accountId, accountName, balance, status, ineligible, etc.
    Uses REST API if available, otherwise falls back to reading the UI dropdown."""
    if self.api_available:
        accounts = self.api_get_trading_accounts()

```

```

        if accounts:
            return accounts

# Fallback: read the MuiSelect dropdown options from UI
try:
    items = self.driver.execute_script("""
        const select = document.querySelector('[role="combobox"]');

        return result;
    """)
    return items or []
except Exception as e:
    self.logger.warning(f"[SWITCH] Could not list accounts from UI: {e}")
    return []

```

Method: TopStepXAccount.switch_account

```
def switch_account(self, account_id=None, account_name_contains=None)
```

Switch to a sub-account via the MuiSelect dropdown. Minimal/fast path: 1. Per-session cache hit → instant return. 2. Read selector text → if already shows target, cache + return. 3. Click selector → click matching → done. No API calls, no _ensure_on_trading_page, no extra DOM scans.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **with self.lock**: enters a context manager.

Code (copy-paste safe)

```

def switch_account(self, account_id=None, account_name_contains=None):
    """Switch to a sub-account via the MuiSelect dropdown.

    Minimal/fast path:
    1. Per-session cache hit → instant return.
    2. Read selector text → if already shows target, cache + return.
    3. Click selector → click matching <li> → done.

    No API calls, no _ensure_on_trading_page, no extra DOM scans.

```

```
def get_account_stats(self)
```

Get TopStepX account statistics from positions tab - required by GUI

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **if** not self.lock.acquire(blocking=False): branches conditionally.
2. **try** block with 0 **except** clauses, plus a **finally**.

Code (copy-paste safe)

```
def get_account_stats(self):

```

Method: TopStepXAccount._get_stats_via_api

```
def _get_stats_via_api(self)
```

Get account stats via REST API (fast path, no Selenium needed). Returns stats dict compatible with `get_account_stats()` format, or None on failure.

Why these Python concepts were used

- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **isinstance check** — Branches on the runtime type of a value. Used when a function accepts more than one input shape (e.g., a string or a list of strings) and needs to handle each.
- **ternary expression** — Uses `x if cond else y` — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. Assigns `accounts = self.api_get_trading_accounts()`.
2. `if not accounts or not isinstance(accounts, list) or len(accounts) == 0:` branches conditionally.
3. Assigns `acct = accounts[0]`.
4. Assigns `self._api_account_id = acct.get('accountId')`.
5. Assigns `acct_name = acct.get('accountName', '')`.
6. Assigns `account_number = 'TopStepX'`.
7. `if 'V2-' in acct_name:` branches conditionally.
8. Assigns `balance = acct.get('balance', 0)`.
9. Assigns `realized_pnl = acct.get('realizedDayPnl', 0)`.
10. Assigns `open_pnl = acct.get('openPnl', 0)`.
11. Assigns `total_pnl = realized_pnl + open_pnl`.
12. Assigns `positions = self.api_get_positions()`.
13. Assigns `open_count = len(positions) if positions else 0`.
14. Assigns `symbol = ''`.
15. ... and 3 more statement(s) in the body.

Code (copy-paste safe)

```
def _get_stats_via_api(self):

Method: TopStepXAccount.place_order

```

def place_order(self, symbol, quantity, side, order_type='market', price=None, tp_dollars=None,
    sl_dollars=None)

```

Generic method to place orders on TopStepX

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **raise** — Raises an exception explicitly. Either signals an invalid argument the caller should fix, or re-raises after logging.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

def place_order(self, symbol, quantity, side, order_type="market", price=None, tp_dollars=None,
    sl_dollars=None):

Method: TopStepXAccount.prepare_buy_order

```
def prepare_buy_order(self, symbol, quantity)
```

THREADING OPTIMIZATION: Prepare BUY order (symbol search, quantity setup) WITHOUT clicking button. Use this before threading to minimize time inside parallel execution. Returns: True if preparation successful, False otherwise

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **raise** — Raises an exception explicitly. Either signals an invalid argument the caller should fix, or re-raises after logging.

Step by step (top-level body)

1. **with self.lock:** enters a context manager.

Code (copy-paste safe)

```

def prepare_buy_order(self, symbol, quantity):
    """
    THREADING OPTIMIZATION: Prepare BUY order (symbol search, quantity setup) WITHOUT clicking button
    Use this before threading to minimize time inside parallel execution.

    Returns: True if preparation successful, False otherwise
    """

```

Method: TopStepXAccount.place_buy_order

```

def place_buy_order(self, symbol, quantity, order_type='market', tp_dollars=None, sl_dollars=None,
    skip_post_trade_setup=False)

```

Place a BUY order on TopStepX with optional post-trade TP/SL setup Args: symbol: Trading symbol (e.g., 'NQM25') quantity: Number of contracts order_type: Order type (default: 'market') tp_dollars: Take profit in dollars sl_dollars: Stop loss in dollars skip_post_trade_setup: If True, skip TP/SL editing in Positions tab. Caller should manually call setup_post_trade_tp_sl_positions() later. Use this in hedging mode to place MT5 trade first for speed.

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **raise** — Raises an exception explicitly. Either signals an invalid argument the caller should fix, or re-raises after logging.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.

Step by step (top-level body)

1. with self.lock: enters a context manager.

Code (copy-paste safe)

```
def place_buy_order(self, symbol, quantity, order_type="market", tp_dollars=None, sl_dollars=None,

Method: TopStepXAccount.place_sell_order

```
def place_sell_order(self, symbol, quantity, order_type='market', tp_dollars=None, sl_dollars=None,
    skip_post_trade_setup=False)
```

Place a SELL order on TopStepX with optional post-trade TP/SL setup Args: *symbol: Trading symbol (e.g., 'NQM25') quantity: Number of contracts order_type: Order type (default: 'market') tp_dollars: Take profit in dollars sl_dollars: Stop loss in dollars skip_post_trade_setup: If True, skip TP/SL editing in Positions tab. Caller should manually call setup_post_trade_tp_sl_positions() later. Use this in hedging mode to place MT5 trade first for speed.*

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **with-statement** — Uses a **with** block, so the resource (file, lock, transaction, MT5 session) is released even if the body raises. Avoids the easy bug of a missed close on the error path.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **raise** — Raises an exception explicitly. Either signals an invalid argument the caller should fix, or re-raises after logging.

Step by step (top-level body)

1. **with self.lock:** enters a context manager.

Code (copy-paste safe)

```
def place_sell_order(self, symbol, quantity, order_type="market", tp_dollars=None, sl_dollars=None,
    skip_post_trade_setup=False):

```

Method: TopStepXAccount.switch_to_order_tab

```
def switch_to_order_tab(self)
```

Switch to the Order tab to access order entry form Returns: bool: True if successful, False otherwise

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

def switch_to_order_tab(self):
    """
    Switch to the Order tab to access order entry form

    Returns:
        bool: True if successful, False otherwise
    """

```

Method: TopStepXAccount._find_position_row

```
def _find_position_row(self, symbol=None)
```

Find the position row in the positions grid

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **list comprehension** — Builds a list in a single expression ([f(x) for x in xs]). Faster than the equivalent for-loop with append, and clearer about intent: this is a transform, not a side-effecting loop.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```

```
def setup_post_trade_tp_sl_positions(self, tp_dollars, sl_dollars)
```

Setup TP/SL in the positions section AFTER trade is placed OPTIMIZED: Edits each field exactly once with no retries for speed

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

Edit the To Make field in the data grid to set TP

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def _edit_to_make_field(self, tp_dollars):
    """Edit the To Make field in the data grid to set TP"""
    try:
        self.logger.info(f"■ Editing To Make field to ${tp_dollars}")

@retry_on_stale_element(max_retries=2, delay=0.5)
def _set_contract_symbol(self, symbol)
```

ULTRA-FAST: Direct symbol entry with minimal waits

Why these Python concepts were used

- **@retry_on_stale_element** — Decorator applied to the function — wraps it so that extra behaviour runs around each call without changing the call site.
- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **raise** — Raises an exception explicitly. Either signals an invalid argument the caller should fix, or re-raises after logging.
- **ternary expression** — Uses x if cond else y — a conditional expression, not a statement. Right tool when both branches produce a value the surrounding expression consumes.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def _set_contract_symbol(self, symbol):
    """

        self.logger.error(f"Failed to click Flatten All button: {e}")
        return False
```

Method: TopStepXAccount._close_individual_positions

```
def _close_individual_positions(self)

    Try to close individual positions if Flatten All is not available
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def _close_individual_positions(self):
    """Try to close individual positions if Flatten All is not available"""
    try:
        # Look for individual position close buttons
        close_buttons = self.driver.find_elements(By.XPATH,
            "//button[contains(text(), 'Close Position')]")

        if not close_buttons:
            self.logger.warning("No individual position close buttons found")
            return False

        for button in close_buttons:
            if button.is_enabled():
                button.click()
                time.sleep(1)
                self._handle_order_confirmation()

        self.logger.info("Individual positions closed")
        return True

    except Exception as e:
        self.logger.error(f"Failed to close individual positions: {e}")
        return False
```

Method: TopStepXAccount._handle_order_confirmation

```
def _handle_order_confirmation(self)

    Handle any order confirmation dialogs that may appear
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.

Step by step (top-level body)

1. **try** block with 1 **except** clause.

Code (copy-paste safe)

```
def _handle_order_confirmation(self):
    """Handle any order confirmation dialogs that may appear"""
    try:
        # Look for confirmation dialogs and click confirm if present
        confirmation_selectors = [
```

```

        "//button[contains(text(), 'Confirm')]",
        "//button[contains(text(), 'YES')]",
        "//button[contains(text(), 'OK')]",
        "//button[contains(text(), 'Submit')]"
    ]

```

Functions

```
def retry_on_stale_element(max_retries=3, delay=1)
    Decorator to retry web operations that may fail due to stale elements
```

Why these Python concepts were used

- **try/except** — Wraps part of the body in **try/except**. The function expects a particular failure mode (network timeout, missing file, parse error) and either recovers or returns a fallback so the caller doesn't have to handle it.
- **f-string** — Builds strings with **f-strings**. Compiled at parse time — the fastest formatting option, and the format spec after the colon controls width, precision, and alignment.
- **raise** — Raises an exception explicitly. Either signals an invalid argument the caller should fix, or re-raises after logging.
- **nested function** — Defines a function inside this function. Usually a closure that captures local variables, or a callback passed to another function.

Step by step (top-level body)

1. Defines a nested function decorator(...).
2. **return** decorator.

Code (copy-paste safe)

```
def retry_on_stale_element(max_retries=3, delay=1):
    """Decorator to retry web operations that may fail due to stale elements"""
```

```

def decorator(func):
    @wraps(func)
    def wrapper(self, *args, **kwargs):
        for attempt in range(max_retries):
            try:
                return func(self, *args, **kwargs)
            except (StaleElementReferenceException, NoSuchElementException) as e:
                if attempt == max_retries - 1:
                    self.logger.error(f"Max retries reached for {func.__name__}: {e}")
                    raise e
                self.logger.warning(
                    f"Retrying {func.__name__} due to stale element (attempt {attempt + 1})")
                time.sleep(delay)
            except Exception as e:
                # Don't retry for other exceptions
                raise e
        return None
    return wrapper
return decorator

```

```
def test_topstepx_connection()

    import traceback
    traceback.print_exc()
finally:
    print("\n■ Disconnecting from TopStepX...")
    account.disconnect()
    print("■ TopStepX test completed")

```

Step 8.4 — Build trader_companion/tradovate.py

What to do. Create the file trader_companion/tradovate.py in your project root and paste in the code shown in this step. The file is **3334** lines long; we walk through it piece by piece below.

Depends on. No internal imports — this file is self-contained and only relies on the standard library plus packages from requirements.txt.

What this file is for. Tradovate-specific scraper and account adapter.

trader_companion/tradovate.py

3334 loc · 1 classes · 0 functions · 17 imports

Tradovate-specific scraper and account adapter. It defines **1** class, across **3,334** lines.

Python concepts demonstrated in this module

• Classes and objects • Comprehensions • Context managers (with-statements) • Dunder methods • Exceptions • f-strings • Lambdas

Imports — what each one is for

```
import os
```

Why imported. Operating-system interface. Path manipulation, environment variables, working-directory operations, exit codes, and thin wrappers around POSIX/Windows syscalls.

Used in this file. os.environ, os.environ.pop, os.getenv, os.path, os.path.dirname, os.path.join

Example. os.path.join(root, 'subdir', 'file.txt') # joins with the OS-correct separator

Other common scenarios.

- os.environ.get('API_KEY') to read environment variables
- os.makedirs(path, exist_ok=True) to create nested directories
- os.listdir(path) to list a directory's contents
- os.remove(path) / os.rename(src, dst) to delete or move a file

- `os.getcwd()` / `os.chdir(path)` to inspect or change the working dir

`import sys`

Why imported. Access to the running interpreter — `argv`, `stdin/stdout`, exit codes, the import search path, and the platform name.

Used in this file. `sys.path`, `sys.path.insert`

Example. `sys.exit(1)` # terminate the process with a non-zero status

Other common scenarios.

- `sys.argv[1:]` reads the command-line arguments
- `sys.path.insert(0, 'extra')` prepends to the import search path
- `sys.stderr.write(msg)` writes to standard error
- `sys.platform` tells you 'win32', 'linux', or 'darwin'
- `sys.modules` is the global cache of already-imported modules

`import time`

Why imported. Timestamps and sleep. Lower-level than `datetime` — works in Unix-epoch seconds.

Used in this file. `time.sleep`, `time.strftime`, `time.time`

Example. `time.sleep(1.5)` # pause this thread for 1.5 seconds

Other common scenarios.

- `time.time()` returns seconds since the epoch
- `time.monotonic()` for measuring elapsed time (never goes backward)
- `time.perf_counter()` for high-precision benchmarking
- `time.strftime` / `time.strptime` mirror the `datetime` versions

`import json`

Why imported. JSON encoding and decoding — the standard wire format for config files, API payloads, and inter-process messages.

Used in this file. `json.dumps`

Example. `json.loads(response.text)` # parse a JSON string to dict

Other common scenarios.

- `json.dumps(obj, indent=2)` for pretty-printing
- `json.dump(obj, file)` / `json.load(file)` for file I/O
- `default=str` handles non-serialisable types like `datetime`
- `object_hook=` customises decoding (e.g., to `dataclass` instances)

`import threading`

Why imported. Threads and synchronisation primitives. Used when work is I/O-bound and the GIL is not a bottleneck (the GIL prevents speed-up on CPU-bound work).

Used in this file. threading.RLock

Example. Thread(target=worker, args=(q,), daemon=True).start()

Other common scenarios.

- Lock / RLock to guard shared state
- Event for one-shot signals between threads
- Queue (from queue) for producer/consumer patterns
- threading.local() for thread-local storage

import logging

Why imported. Structured, levelled logging. Replaces print() with filterable, formattable output that can route to files, stderr, syslog, or HTTP endpoints.

Used in this file. logging.INFO, logging.basicConfig, logging.debug, logging.error, logging.info, logging.warning

Example. logging.getLogger(__name__).info('connected to %s', host)

Other common scenarios.

- .debug() / .info() / .warning() / .error() / .exception()
- logger.exception() captures the current traceback automatically
- logging.basicConfig(level=logging.INFO) for quick setup
- Handlers and Formatters route logs to files / streams / syslog

import random

Why imported. Pseudo-random numbers — fine for jitter, sampling, shuffling. NEVER for security; use secrets for that.

Used in this file. *No direct attribute access detected — likely imported for side effects, re-export, or string references.*

Example. random.uniform(0.5, 1.5) # backoff jitter

Other common scenarios.

- random.choice(seq) picks one item
- random.shuffle(list) rearranges in place
- random.seed(n) makes the sequence reproducible
- random.sample(seq, k) draws k unique items

import hashlib

Why imported. Cryptographic hash functions — SHA-256, MD5, BLAKE2.

Used in this file. *No direct attribute access detected — likely imported for side effects, re-export, or string references.*

Example. hashlib.sha256(b'hello').hexdigest()

Other common scenarios.

- Pass data in chunks via `.update()` to hash large files
- Use sha256 / sha512 for integrity; never MD5 or SHA-1 for security
- For password hashing use `bcrypt/argon2`, NOT raw `hashlib`

`import tempfile`

Why imported. Temporary files and directories that clean themselves up.

Used in this file. `tempfile.gettempdir`

Example. with `tempfile.TemporaryDirectory()` as `d`: ...

Other common scenarios.

- `tempfile.NamedTemporaryFile(delete=False)` for a real path on disk
- `tempfile.mkstemp()` returns a low-level (fd, path) pair

`from selenium import webdriver`

Why imported. Browser automation. Drives a real Chrome instance — the fallback for scraping prop-firm dashboards that have no API.

Used in this file. `webdriver`

Example. `driver.get(url); driver.find_element(By.ID, 'login')`

Other common scenarios.

- `WebDriverWait + expected_conditions` for reliable waits
- `ChromeOptions().add_argument('--headless=new')`
- `execute_script(js, *args)` reaches into the page for things the DOM API can't express

`from selenium.webdriver.common.by import By`

Why imported. Browser automation. Drives a real Chrome instance — the fallback for scraping prop-firm dashboards that have no API.

Used in this file. `By`

Example. `driver.get(url); driver.find_element(By.ID, 'login')`

Other common scenarios.

- `WebDriverWait + expected_conditions` for reliable waits
- `ChromeOptions().add_argument('--headless=new')`
- `execute_script(js, *args)` reaches into the page for things the DOM API can't express

`from selenium.webdriver.common.keys import Keys`

Why imported. Browser automation. Drives a real Chrome instance — the fallback for scraping prop-firm dashboards that have no API.

Used in this file. `Keys`

Example. `driver.get(url); driver.find_element(By.ID, 'login')`

Other common scenarios.

- WebDriverWait + expected_conditions for reliable waits
- ChromeOptions().add_argument('--headless=new')
- execute_script(js, *args) reaches into the page for things the DOM API can't express

```
from selenium.webdriver.support.ui import WebDriverWait
```

Why imported. Browser automation. Drives a real Chrome instance — the fallback for scraping prop-firm dashboards that have no API.

Used in this file. WebDriverWait

Example. driver.get(url); driver.find_element(By.ID, 'login')

Other common scenarios.

- WebDriverWait + expected_conditions for reliable waits
- ChromeOptions().add_argument('--headless=new')
- execute_script(js, *args) reaches into the page for things the DOM API can't express

```
from selenium.webdriver.support import expected_conditions as EC
```

Why imported. Browser automation. Drives a real Chrome instance — the fallback for scraping prop-firm dashboards that have no API.

Used in this file. EC

Example. driver.get(url); driver.find_element(By.ID, 'login')

Other common scenarios.

- WebDriverWait + expected_conditions for reliable waits
- ChromeOptions().add_argument('--headless=new')
- execute_script(js, *args) reaches into the page for things the DOM API can't express

```
from selenium.webdriver.common.action_chains import ActionChains
```

Why imported. Browser automation. Drives a real Chrome instance — the fallback for scraping prop-firm dashboards that have no API.

Used in this file. ActionChains

Example. driver.get(url); driver.find_element(By.ID, 'login')

Other common scenarios.

- WebDriverWait + expected_conditions for reliable waits
- ChromeOptions().add_argument('--headless=new')
- execute_script(js, *args) reaches into the page for things the DOM API can't express

```
from selenium.webdriver.chrome.options import Options
```

Why imported. Browser automation. Drives a real Chrome instance — the fallback for scraping prop-firm dashboards that have no API.

Used in this file. Options

Example. `driver.get(url); driver.find_element(By.ID, 'login')`

Other common scenarios.

- `WebDriverWait + expected_conditions` for reliable waits
- `ChromeOptions().add_argument('--headless=new')`
- `execute_script(js, *args)` reaches into the page for things the DOM API can't express

```
from dotenv import load_dotenv
```

Why imported. `python-dotenv` — load `.env` files into `os.environ` for twelve-factor configuration in development.

Used in this file. `load_dotenv`

Example. `load_dotenv()` # call once at process start

Other common scenarios.

- `dotenv_values('.env')` returns a dict without polluting `os.environ`
- Use a real secret store in production (vault, AWS SM, etc.)

Module constants

Each line below is followed by a plain-English note explaining what it does and why it is written that way.

```
DEFAULT_SYMBOL = os.getenv('TRADOVATE_SYMBOL') or 'MNQM6'
```

Module-level constant — bound once at import time and referenced from the functions and classes below.

```
DEFAULT_TP = os.getenv('TRADOVATE_TAKEPROFIT_TICKS')
```

Reads `TRADOVATE_TAKEPROFIT_TICKS` from the environment. Returns `None` if unset.

```
DEFAULT_SL = os.getenv('TRADOVATE_STOPLOSS_TICKS')
```

Reads `TRADOVATE_STOPLOSS_TICKS` from the environment. Returns `None` if unset.

Classes

```
class TradovateAccount
```

Tradovate trading automation class with robust Selenium-based web automation. Handles login, symbol selection, order placement, ATM configuration, and account statistics. Ensures single Chrome instance per account to prevent resource conflicts.

```
_chrome_instances = {}
```

Code (copy-paste safe)

```
class TradovateAccount:
    """
    Tradovate trading automation class with robust Selenium-based web automation.
    Handles login, symbol selection, order placement, ATM configuration, and account statistics.
    Ensures single Chrome instance per account to prevent resource conflicts.
    """
